First Quarter 2007 Progress Report

File: 643.002

Dear Mr. Jones:

Enclosed please find the First Quarter 2007 Progress Report for the subject sites.

Should you have any questions regarding the enclosed, please feel free to contact me.

Thank you.

Very truly yours,

BARTON & LOGUIDICE, P. C.

Andrew J. Barber

May, 2007

1.0 Introduction

This First Quarter 2006 Progress Report (1Q07) is being submitted pursuant to the Orders on Consent between Photocircuits Corporation and the New York State Department of Environmental Conservation (NYSDEC) dated March 1997 (31 Sea Cliff Avenue) and February 1998 (45A Sea Cliff Avenue).

During the First Quarter of 2007, the following was accomplished:

- One groundwater sampling event was conducted for monitoring wells located on both the 31 and 45A Sea Cliff Avenue sites during the period of April 2-3.
- Maintenance activities were performed on the Soil Vapor Extraction (SVE) system at the 45A Sea Cliff Avenue.
- Maintenance activities were performed on to the hydraulic control system at the 31 Sea Cliff Avenue site.

This report serves a continuation of the quarterly reports for the Photocircuits sites, which were suspended during the events surrounding the Photocircuits bankruptcy proceedings.

2.0 Discussion of Results

2.1 SVE System at 31 Sea Cliff Avenue

The SVE system is inactive.

2.2 Bioremediation Pilot Test at 31 Sea Cliff Avenue

2.2.1 Background

The bioremediation pilot test was started during the week of August 28, 2000 when Terra Systems conducted the injection of a nutrient solution (substrate) into the subsurface at the 31 Sea Cliff Avenue site. Following the injection, groundwater samples were collected from the following monitoring wells/points: MW-7, MW-14, SMP-1, DMP-1, SMP-3, DMP-3, SMP-4 and DMP-4. These wells/points were sampled again on October 18-19, December 20, 2000, March 27-28, 2001 and July 11-12, 2001; the March and July sampling events included several wells located along Sea Cliff Avenue (MW-8, MW-9, MW-12 and MW-13) along with the wells sampled during the previous events. By letter dated October 25, 2001, NYSDEC authorized an additional injection of substrate that had been recommended by Photocircuits. A first phase of additional substrate injection was

conducted during the period of February 25 to March 3, 2002; during this period, slightly over 5,000 gallons of substrate was injected (as reported in the 1Q 02 report). On April 29, 2002, an additional injection of 5,777 gallons of substrate was injected using the injection points that had been installed during the February-March injection event. Sampling events conducted in 2002 were January 8-10, April 2-4, June 25-26 and October 2-3. Sampling in 2003 was conducted on January 13-15, April 28-29 and December 16-17. Sampling in 2004 was conducted on March 15-17 and June 21-23.

2.2.2 Summary of Recent Activities

The most recent sampling events were conducted on July 20-21, 2005, November 6-7, 2006 and April 2-3, 2007; the results from these sampling events are provided in Appendix A of this report (Note: well MW-7 was not sampled during this event as it was filled with oil substrate).

A status report on the pilot test (including the data from the samples collected in July 2005, November 2006 and April 2007) was prepared by Terra Systems and is included as Appendix B of this report. The main conclusions of the report are as follows

- The addition of the edible oil substrate has enhanced the extent and rate of chlorinated solvent biodegradation at the 31 sea Cliff Avenue site; conditions continue to be favorable for biodegradation based on several indicators, most notably, the large decreases in 1,1,1-trichloroethane and 1,1-dichloroethane in wells SMP-3 and DMP-3.
- Over the 79 months of operation, the overall average sum of VOCs has decreased by 80%; degradation rates have slowed as substrate levels have dropped below optimum levels in some locations.
- Bioremediation is the primary treatment technology best suited for continued contaminant destruction at the site.

The Terra Systems report (dated May 17, 2007) again contains a recommendation for additional substrate injection. A letter was sent to NYSDEC (dated April 2, 2004) requesting permission to perform the additional injection. An FFS was prepared for the 31 Sea Cliff Avenue site and submitted to the NYSDEC in Q4 06. The FFS evaluated four different remedial alternatives, and recommended continuing and enhancing the existing bioremediation program coupled with hydraulic control as the remedy for the site.

2.3 IRM at 45 Sea Cliff Avenue

2.3.1 Background

As discussed in the 4Q 2000 report, SVE/AS equipment was procured and delivered to the site. The SVE/AS system consists of a 10 horsepower (hp) regenerative blower and 5 hp compressor, along with electrical controls, filters, moisture separators, and valves; the system is contained within an insulated trailer, which has been located just outside of Building 7. Following delivery, the system components were connected to the piping networks for the AS and SVE wells. Two 1200 lb activated carbon adsorbers were attached in series to the blower outlet to treat recovered vapors. The SVE system was started on November 1, 2000; because the initial contaminant concentrations were relatively high, the AS portion of the system was not started. The AS component of this system was started on March 28, 2001. The system was down from April 20-24 due to an electrical problem. The system was down most of June and July due to equipment overheating; the system was re-started on July 30 and shut down on September 20.

Monitoring data was presented in the 2Q01 report, including data from sampling of individual SVE wells (March 2001) and sampling of total SVE system effluent over time. Prior to the start of the AS component, the relationship of total contaminant mass removal versus time was clearly becoming asymptotic. The start of the AS component increased contaminant mass recovery somewhat (see the April 2001 sample results). However, the results of the May 2001 vapor sample indicate that mass removal versus time relationship became asymptotic. We concluded at that time that we demonstrated that there was little or no residual contamination at that location, and that further contaminant removal is infeasible.

Based on results from the January 2002 groundwater sampling event, Photocircuits proposed extending the SVE/AS system at the 45A Sea Cliff Avenue site from the west side to the east side of Building 7. The basis for the extension of the system and the proposed piping and equipment layout were provided in the February 13, 2002 letter to NYSDEC.

The SVE wells and AS points were installed at the proposed locations on the east side of Building 7 in late February, 2002 in preparation for the extension of the system. After field evaluation, it was decided that it would be more efficient to move the aboveground portions of the system (equipment trailer, carbon vessels) to the east side of Building 7 rather than to extend their operation by piping from the west side to the east side of Building 7, as originally proposed. The trailer and carbon vessels were moved in April, and electrical service was also provided to the new location in April. Piping and mechanical connections were completed in early May; the original blower malfunctioned and a smaller replacement blower was installed.

The SVE portion of the system was started on May 8, 2002, and a sample of the total system effluent, prior to treatment, was collected; tetrachloroethene was detected at a concentration of 5.3 ppmv. Another effluent sample was collected on June 26;

tetrachloroethene was detected at a concentration of 142 ppmv and trichloroethene was detected at a concentration of 2 ppmv. Further sampling in 2002 was conducted on October 3, December 12 (tetrachloroethene was detected at 1.2 and 1.1 ppmv in these two samples, respectively). The AS portion of the system was started on December 11, 2002. On May 1, 2003, the system was modified to also extract vapor from monitoring well MW-4S; the well was fitted with a cap and connected to the SVE portion of the system.

On May 28, 2004, a meeting/conference call was held between Photocircuits and NYSDEC to discuss, among other issues, procedures for documenting completion of remedial activities at the 45A Sea Cliff Avenue site. A work plan was submitted to NYSDEC as a follow-up to this meeting, and approval of the amended work plan was received by letter dated September 9, 2004; one of the tasks in the work plan was pulsing the SVE system to determine whether residual contamination is present in the subsurface. The SVE system was shut down on June 23, 2004 as part of the pulsing task; the system was re-started September 28, 2004 and sampled per the approved work plan.

Concentrations of tetrachloroethene in effluent samples for 2003-2004 are provided in the following table:

Concentrations of tetrachloroethene (ppmv) in AS/SVE system effluent (east side Bldg 7 location)						
Jan-03	May-03	May-03	Aug-03	Dec-03	Mar-04	Sep-04
1.0	0.9	1.1	1.1	0.03	0.00049	2.0

Concentrations of tetrachloroethene (ug/L) in samples from monitoring well MW-4S over time are summarized in the following table:

Concentrations of tetrachloroethene (ug/L) in MW-4S														
2002				2003				2004				2005	2006	2007
Jan	Apr	Jun	Oct	Jan	Apr	Aug	Dec	Mar	Jun	Sep	Dec	Jul	Nov	Apr
1240	1910	2200	2510	3600	1420	118	180	83	29	10	110	47	35	30

Another task in the approved work plan was the collection of four soil vapor samples in and around Building 7 using summa canisters. The sampling was conducted on September 27-28, 2004 per the approved work plan, and the results were reported in the 3Q04 Report. The concentrations of tetrachloroethene detected in Samples 1 and 2 indicated that there was additional contaminant mass present in the vadose zone in the area of those samples. To address this contaminant mass, the SVE blower was brought back to the west side of Building 7 (along with activated carbon drums to treat the blower effluent). The blower was connected to two existing SVE wells (located within the area of Samples 1 and 2) by modifying the existing piping; the re-configured system was started on October 27, 2004. Samples of the blower influent (combined influent from

both SVE wells) were collected on December 14, 2004 and July 21, 2005; the samples contained 11 and 1.2 ppmv of tetrachloroethene, respectively.

2.3.2 Summary of Recent Activities

A report summarizing the IRM was prepared and submitted to NYSDEC in Q4 06; the report demonstrated that the remedial goals had been achieved, such that the IRM should be considered as the final remedy for the site. The report requested the preparation of a Record of Decision (ROD) that would dictate no further action for the site.

2.4 Hydraulic Control along Sea Cliff Avenue

2.4.1 Background

A meeting was held with NYSDEC on October 11, 2001 to discuss the progress of the bioremediation pilot test. Although there was substantial disagreement between Photocircuits and the NYSDEC over the progress of the bioremediation pilot test and the need for groundwater remediation, Photocircuits agreed to review available options for containment of groundwater along the northern boundary of the Photocircuits site (31 Sea Cliff Avenue). Photocircuits conducted the review of remedial options, and by letter dated October 26, 2001, Photocircuits presented the results of the review. Photocircuits recommended the use of hydraulic control. Photocircuits submitted a work plan for the performance of pumping tests necessary for the design of a hydraulic control system on November 13, 2001; following receipt of verbal comments from NYSDEC, Photocircuits submitted a revised work plan on December 7, 2001. Approval for implementation of the work plan was received from NYSDEC by letter dated December 19, 2001. The pumping tests were performed in January, 2002 and the remedial design report was submitted to NYSDEC on April 11, 2002. NYSDEC approval of the remedial design was received in a letter dated September 19, 2002.

Four recovery wells were installed in January, 2003. The fifth recovery well could not be installed due to the proximity of numerous underground utility lines. Groundwater modeling conducted for the design of the hydraulic control system (appended to the remedial design report/work plan) indicated that configuration of the four wells is also capable of providing hydraulic control in the subject area. The wells were installed to depths of 80 feet below grade and were constructed as described in the work plan.

The pumps, piping and control systems were installed during the week of April 28, 2003. The layout of the piping and controls are provided on the attached figure. The system was started up on May 1, 2003, with each well pumping at an initial flow rate of one gallon per minute (gpm). On May 20, the pumping rate for each well was increased to three gpm. Data and figures presented in the 2Q03 Report demonstrated that hydraulic control was being achieved in the area hydraulically downgradient of the bioremediation

pilot test area. During the August sampling event, it was noted that the pumping rate of the wells had reduced to roughly one gpm, although the pump controllers had not been adjusted. We believe that the reduction in pumping resulted from an interruption in the compressed air supply to the pumps; compressed air is supplied by the facility, and periodic interruptions occur due to maintenance activities. Because the pump controllers are pneumatic, the pump cycle logic re-sets upon re-start. We had planned to provide a back-up compressed air supply to allow the pumps to maintain the three gpm pumping rate, however, an accumulation of weathered soybean oil was detected in well MW-14 during the December 2003 sampling event and again during the March 2004 event. This well is located directly downgradient of the bioremediation pilot test area; fresh soybean oil was found in this well on three occasions in 2002, but has not been detected for roughly a year. We believe that the presence of the weathered soybean oil indicates that the hydraulic control system has not only been collecting contaminated groundwater, but may have accelerated the movement of contaminants from the bioremediation pilot test area. As a result, we have continued to operate the hydraulic control system at the lower flow rate (roughly 1 gpm per well). We believe that the water quality and water level data demonstrate that hydraulic control is being achieved, without the undesirable effects of the localized increase in groundwater velocity (i.e. – pulling the soybean oil from the bioremediation pilot test area).

2.4.2 Summary of Recent Activities

Soybean oil has not been evident in well MW-14 since the March 2004 sampling event. Some clogging in the individual pumping systems has been evident in 2005 and 2006 due precipitated iron, which is the result of the bioremediation program (naturally-occurring +3 valence iron oxides in the formation is chemically reduced to the more soluble +2 valence state). As the chemically reduced groundwater moves to the recovery well, it is mixed with air (oxygen) within the pump (which operates using compressed air); the iron is then re-oxidized and precipitates within the discharge line. The clogs were removed either mechanically or with compressed air, or the discharge tubing was replaced. We do not anticipate interruption of system operation as we continue quarterly sampling and maintenance activities.

3.0 Schedule

The planned schedule of activities for the next few months is attached.

RE: Semi-Annual

Dear Peter Takach:

Order No.: 0704031

American Analytical Laboratories, LLC. received 16 sample(s) on 4/3/2007 for the analyses presented in the following report.

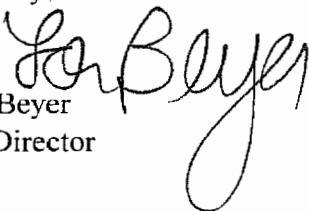

Samples were analyzed in accordance with the test procedures documented on the chain of custody and detailed throughout the text of this report.

The limits provided in the data package are analytical reporting limits and not Federal or Local mandated values to which the sample results should be compared.

There were no problems with the analyses and all data for associated QC met laboratory specifications. If there are any exceptions a Case Narrative is provided in the report.

If you have any questions regarding these tests results, please do not hesitate to call (631) 454-6100 or email me directly at lbeyer@american-analytical.com.

Sincerely,

Lori Beyer
Lab Director

American Analytical Laboratories, LLC.

DATA REPORTING QUALIFIERS

For reporting results, the following "Results Qualifiers" are used:

Value	If the result is greater than or equal to the detection limit, report the value
U	Indicates the compound was analyzed for but was not detected. Report the minimum detection limit for the sample with the U, i.e. "10U". This is not necessarily the instrument detection limit attainable for this particular sample based on any concentration or dilution that may have been required.
J	Indicates an estimated value. The flag is used: (1) When estimating a concentration for a tentatively identified compound (library search hits, where a 1:1 response is assumed.) (2) When the mass spectral data indicated the identification, however the result was less than the specified detection limit greater than zero. If the detection limit was 10ug/L and a concentration of 3ug/L was calculated report as 3J. This flag is used when similar situations arise on any organic parameter i.e. Pesticide, PCBs and others.
B	Indicates the analyte was found in the blank as well as the sample report "10B".
E	Indicates the analytes concentration exceeds the calibrated range of the instrument for that specific analysis.
D	This flag identifies all compounds identified in an analysis at a secondary dilution factor.
P	This flag is used for Pesticide / PCB target analyte when there is >25% difference for detected concentrations between the two GC Columns. The higher of the two values is reported on Form I and flagged with a "P".
N	This flag indicates presumptive evidence of a compound. This is only used for tentatively identified compounds (TICs), where the identification is based on a mass spectral library search. It applies to all TIC results. For generic characterization of a TIC, such as chlorinated hydrocarbon, the flag is not used.
H	Indicates sample was received and/or analyzed outside of The method allowable holding time

1.0 EXECUTIVE SUMMARY

In August 2000, Photocircuits Corporation initiated a pilot study at its 31 Sea Cliff Ave. property to treat chlorinated volatile organic compounds (VOC) using in situ anaerobic bioremediation. The site is characterized by VOC contamination of a sandy, silt, and gravel aquifer. Monitoring data indicate that some biodegradation of these contaminants was occurring at the site prior to the start of the pilot study. The two primary objectives of this pilot study are to 1) evaluate the use of substrate injection to enhance in situ anaerobic biological degradation of chlorinated VOCs in the study area and 2) obtain operating and performance data to optimize the design and operation of a full-scale system. During the operational period of this pilot study, there is no emphasis on reducing any contaminants to a specific regulatory level.

The study area, which encompasses a triangular area roughly 92 feet wide, 157 feet long, and 60 feet deep, underlies the former drum storage area of the Photocircuits Corporation facility. Prior to the start of the pilot test, total chlorinated contaminant concentrations in wells within the pilot area ranged from 457 to 539,000 µg/L. The initial pilot bioremediation system consisted of six injection points in a line spaced about 15 to 20 feet apart. A slow release substrate (SRSTM) containing edible soybean oil was designed to provide a slow release food grade carbon source over a period in excess of twelve months. A total of 3,600 gallons of the soybean oil emulsion was injected. The substrate concentrations were selected based on previous experience.

An additional 5,722 gallons of the emulsified substrate was injected in months 17 and 19 (February and April 2002) at twelve injection points in a full-scale treatment cell. VOC and substrate concentrations have been monitored twenty times over a seventy-nine month period at eight wells spaced throughout the treatment area. VOC and substrate concentrations have also been monitored at ten wells downgradient of the treatment area to determine if the substrate has migrated outside of the area and if the substrate amendment has affected these wells.

The system has been operating since August 31, 2000. Substrate monitoring data after the first injection indicated that substrate was delivered throughout the treatment cell with the highest substrate levels found in well MW-14. In the initial injection event in August 2000, the emulsion moved into this well from several of the injection points and displaced much of the contaminated groundwater within this well. Well MW-7 has contained the emulsion since April 2002 and has not been sampled. Contaminant levels had increased in MW-7 between August 2000 and January 2002 when the last sample was collected from this well. An increase in total VOCs has also been observed in well MW-14 since the first injection of substrate in August 2000. Desorption of contaminants adsorbed to the soil due to enhanced biological activity may be contributing to the increased contaminant concentrations in MW-14 and MW-7. Contaminants that partitioned into the injected oil may also be released. Where substrate levels were above 50 mg/L, significant declines in total VOC concentrations (90-98%) were generally observed. Wells MW-14, MW-7 (through 1/8/02), and DMP-4 have shown increased total volatiles concentrations since September 2000. The average total contaminant concentrations within the treatment cell (excluding MW-7) have fallen by as much as 84.1% since September 2000. The average total volatile percent removal was 79.8% in April 2007. The substrate reinjection in February and April 2002 increased the TOC concentrations in all wells within the treatment cell. In April 2007, TOC levels ranged from 22 mg/L in DMP-3 to 620 mg/L in MW-14 with an

average of 108 mg/L in the seven wells sampled within the treatment cell. TOC levels in four of the seven wells were above the target level of 50 mg/L. The concentrations of TOC have dropped considerably in wells SMP-1, DMP-1, SMP-3, DMP-3, and SMP-4 since the last injection event in 2002. The concentrations of sulfate, a competing electron acceptor were higher in wells SMP-1, DMP-3, and SMP-4 in the April 2007 sampling event than the previous event in November 2006.

The average percent removal of total volatiles increased from 31.9% in July 2005 to 79.8% in April 2007 largely as a result of decreased concentrations of 1TCA and 1DCA in SMP-3 and DMP-3. 1TCA concentrations decreased in SMP-3 from 51,000 to 6,900 µg/L and in DMP-3 from 40,000 to 6,400 µg/L over this period. The 1DCA concentrations in SMP-3 decreased from 28,000 to 700 µg/L and in DMP-3 from 44,000 to 14,000 µg/L. The CA concentrations in these wells decreased as reductive dechlorination became limited due to availability of substrate. In April 2007, the concentrations of TOC were 83 mg/L in SMP-3 and 22 mg/L in DMP-3. There might have been a release of the parent compound 1TCA adsorbed into the oil or undegraded 1TCA from an upgradient location that was not adequately treated before it reached wells SMP-3 and DMP-3.

Injection of additional substrate is recommended to remove the competing electron acceptors and promote further dechlorination.

2.0 INTRODUCTION

The enclosed report describes the field study of *in situ* anaerobic bioremediation of a chlorinated solvent plume at the Photocircuits Corporation's 31 Sea Cliff Avenue, Glen Cove, NY facility. The study, which was initiated on August 31, 2000, has the following objectives:

- Determine if the addition of a food grade carbon source will enhance the extent and rate of chlorinated solvent biodegradation at the site.
- Determine the rate of chlorinated solvent biodegradation to estimate the time frame required for contaminant removal.
- Determine if the food grade carbon source can be adequately distributed in the formation such that the microorganisms can utilize it.
- Determine what role bioremediation technology has in the overall remediation strategy for the site.

3.0 BACKGROUND

The Photocircuits Corporation's 31 Sea Cliff Avenue facility, Glen Cove, New York is located on the north shore of Long Island. The plant site is bordered on the north by a light industrial area, to the south and east are arterial roads, and to the west by railroad tracks. The site is generally flat and is covered by manufacturing buildings and parking lots.

3.1 Site Geology/Hydrology

Based on analysis of soil borings and details of well construction at the Photocircuits site, the surficial deposit below the facility is primarily composed of interbedded sand, silt, gravel, and clay layers.

3.2 Nature and Extent of Contamination

The groundwater at the facility has been impacted by chlorinated ethene and chlorinated ethane compounds from various sources. Prior to the start of the pilot test, total volatile organic contaminant concentrations (TVOC) in groundwater ranged from 457 to 539,000 µg/L. Generally, the contamination extends to approximately 90 feet below ground surface (bgs) with the highest concentrations in the 20 to 50 ft. bgs zone.

3.3 Rationale for Use of Technology

As part of the technology review program, Photocircuits Corporation engaged Terra Systems, Inc. (TSI) to conduct an anaerobic bioremediation field pilot study at the facility. The study, which encompasses a triangular area roughly 92 feet wide and 157 long that had been used for drum storage, commenced in August-September, 2000. Eight monitoring points (MW-14, MW-7, SMP-1, DMP-1, SMP-3, DMP-3, SMP-4, and DMP-4) are being utilized to track the progress of the pilot study and full-scale implementation. Beginning in March 2001, groundwater samples were also collected from 4 additional wells (MW-8, MW-9, MW-12, and MW-13) to determine if any of the injected substrate had migrated away from the study area. Wells MW-10 and MW-11 were monitored in January 2002, January 2003, and June 2004. The locations of these wells are shown in Figure 1. It should be noted that these wells are not expected to be impacted by the bioremediation study. Recovery wells RW-1, RW-2, RW-3, and RW-4 were installed in 2003 and have been sampled since December 2003. Well RW-2 was not sampled in September 2004 because of the accumulation of material in the pump discharge line. Well RW-4 was not sampled in April 2007.

Ground surface in the vicinity of the study area is about 60 feet above mean sea level (msl). In the treatment area, wells are screened between 10 and 52 feet msl. Downgradient wells MW-8, MW-10, and MW-11 are deep monitoring wells and wells MW-9, MW-12, and MW-13 are shallow wells. The screen intervals for the wells are shown below:

- Well MW-14 10 to 20 feet msl
- MW-7 37 to 52 feet msl
- SMP-1 50 to 52 feet msl

- SMP-3 45 to 47 feet msl
- SMP-4 45 to 47 feet msl
- DMP-1 40 to 42 feet msl
- DMP-3 35 to 37 feet msl,
- DMP-4 38 to 40 feet msl
- MW-8 -111 and -96 feet msl
- MW-9 31 to 46 feet msl
- MW-10 -72 to - 57 feet msl,
- MW-11 -112 to -97 feet mls
- MW-12 9 to 19 feet msl, and
- MW-13 11 to 21 feet msl.

Historical data indicates that anaerobic biodegradation is occurring at the site as evidenced by the presence of daughter products from the breakdown of tetrachloroethene (PCE) and trichloroethene (TCE) including cis-1,2-dichloroethene (cDCE), trans-1,2-dichloroethene (tDCE), vinyl chloride (VC), and ethene. Acetylene can be produced by the abiotic reaction of PCE or TCE with ferrous sulfide (Butler and Hayes 2000). 1,1,1-Trichloroethane (1TCA) breaks down to 1,1-dichloroethene (1DCE), 1,1-dichloroethane (1DCA), chloroethane (CA), and ethane. However, VC and ethene can also be generated from the breakdown of the 1TCA, 1DCA, and 1DCE. Based on a review of the site historical data, it appears that the biological degradation process is limited by the availability of organic carbon.

3.4 Technology Description

Anaerobic bioremediation, also referred to as reductive dechlorination, of chlorinated solvents is a well documented process that converts chlorinated ethenes and ethanes to innocuous gases.

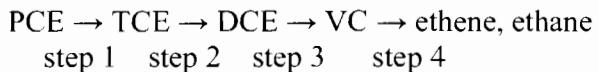

The following technology description is from a report entitled “Cost and Performance Report – In Situ Anaerobic Bioremediation Pinellas Northeast Site Largo, Florida” prepared for the U.S. Department of Energy (1998) by Sandia National Laboratories and Hazardous Waste Remedial Actions Program.

Bacteria metabolize soluble organic and inorganic compounds to provide energy for the growth and maintenance of bacterial cells. The complex organic molecules that bacteria consume are converted to new cells and various simpler compounds, such as carbon dioxide, that are released back into the environment. This process is referred to as biodegradation. Biodegradation has been used very cost effectively for more than a century in public and industrial wastewater treatment systems. Since bacteria occur naturally in both soil and ground water environments, bioremediation technologies attempt to stimulate the activity of these naturally occurring (or introduced bacteria) to degrade contaminants in a cost-effective manner. Bioremediation is being considered more often as the processes that control the biological degradation of contaminants in soil and ground water become better understood.

In order to produce new bacterial cells, bacteria require carbon, nitrogen, phosphorus, and energy sources, as well as a number of trace minerals. Electrons are released by the biochemical reactions that metabolize complex organic compounds for energy. Biological systems capture this biochemical energy through a series of electron transfer (redox) reactions. The bacteria that

are most commonly used in bioremediation systems use organic compounds as their source of carbon and energy; these carbon compounds are referred to as electron donors. Bacterial respiration requires that some chemical compound is available to act as a terminal electron acceptor. Common electron acceptors used by bacteria include oxygen, nitrate, sulfate, Fe^{3+} , and carbon dioxide.

Recently, a class of anaerobic bacteria has been identified that uses halogenated organic compounds as their electron acceptors. The chlorinated VOCs present in the soil and ground water at the Northeast site are among the halogenated organic compounds that can be used in this manner. Halogenated compounds have a high oxidation state; and when a halogen (e.g. chlorine) is chemically replaced by hydrogen, the oxidation state of the chemical is reduced. This process is referred to as reductive dehalogenation, and it forms the basis of the anaerobic process used by the *in situ* bacteria at the Photocircuits site. Under anaerobic conditions, chlorinated compounds can be degraded via reductive dehalogenation reactions to successively lower chlorinated degradation products, and finally to compounds of significantly lower toxicity. This process is illustrated for PCE below.

Biological activity is frequently limited by the availability of a single growth factor (e.g. electron acceptor, electron donor, nitrogen, etc.) and supplying the proper growth factor can often stimulate bacterial growth and biodegradation rates. For *in situ* bioremediation applications, nutrients or electron acceptors are often injected into the contaminated area to enhance the existing microbial degradation processes. Effectively delivering nutrients requires that factors such as site permeability and geochemistry be considered. Each class of contaminant varies in its susceptibility to biodegradation and factors such as aquifer oxidation-reduction potential, microbial ecology, and contaminant toxicity will affect the success of bioremediation at a site. The effective application of *in situ* bioremediation therefore depends upon careful consideration of the geologic and hydrologic properties at the site and on the type and concentration of contaminants to be treated.

Evaluations of the monitoring data from the Photocircuits site suggested that microbial dechlorination is occurring naturally. cDCE and VC are degradation products of TCE that were measured in high concentrations, but were not contaminants originally disposed of at the site, which suggests that a population of dechlorinating microorganisms is relatively active at Photocircuits

The report continues on to outline the technology advantages and disadvantages which are listed below:

Technology Advantages

- Contaminants are treated *in situ* with little waste generation
- Contaminant degradation can be relatively fast
- Bioremediation is capable of reducing contaminants to very low levels

- The process stimulates a microbial population that can continue to feed off the dissolved phase of a continuing source after nutrient injection ceases, and
- Often provides a low overall remediation cost relative to other technologies.

Technology Disadvantages

- Contaminant degradation enhancement is dependent on adequate nutrient delivery to all areas of contamination before the nutrients are directly metabolized, which often is primarily a function of site hydrogeology and the appropriate mixing of nutrients, contaminants, and active microbes,
- Site conditions (e.g. soil and ground water chemistry, reductive processes, etc.) must be conducive to the stimulation of biological activity to be effective,
- Bioremediation will not directly degrade contaminants occurring in an immiscible phase,
- High concentrations of contaminants often are toxic to microorganisms,
- Bioremediation may be difficult to optimize at sites with multiple contaminants of concern,
- Incomplete biodegradation of contaminants can lead to the generation of degradation products that are just as toxic or even more so than the parent contaminants, and
- Regulatory concerns over chemical injections into aquifers.

4.1 Study Area

The study area encompasses a triangular area roughly 92 feet by 157 feet with a contaminated interval of 50 feet (from the water table at 10 feet to 60 feet) underlies the former drum storage area of the Photocircuits Corporation 31 Sea Cliff Ave, Glen Cove, NY facility. Eight monitoring points (MW-14, MW-7, SMP-1, DMP-1, SMP-3, DMP-3, SMP-4, and DMP-4) are being utilized to track the progress of the enhanced anaerobic bioremediation treatment.

Beginning in March 2001 groundwater samples were also collected from four additional wells (MW-8, MW-9, MW-12, and MW-13) to determine if the injected substrate had migrated away from the study area. Wells MW-10 and MW-11 were sampled in January 2002, January 2003, and June 2004. It should be noted that the downgradient wells are not expected to be impacted by the bioremediation project. Recovery wells RW-1, RW-2, RW-3, and RW-4 were first monitored in December 2003.

4.2 Technical Challenges

The key technical challenges for this study are:

- ability to move a carbon source throughout the contaminated area;
- estimation of quantity of chlorinated compounds
- determination of minimum level of TOC required to optimize reductive dechlorination

4.3 Key Design Criteria

The in situ anaerobic bioremediation pilot system was designed for two main objectives;

- develop a nutrient delivery system capable of providing a mixture of nutrients to the subsurface within the heterogeneous aquifer, such that the nutrients will be delivered to all levels in the treatment area within an approximately 24 month operating period, and
- deliver a sufficient quantity of substrate to the treatment area to last for approximately 24 months.

4.4 Treatment System Schematic and Operation

The test area was injected with emulsified soybean oil in August 29 to September 1, 2000. The key objective of the pilot study is to determine if the addition of a food grade carbon source will enhance the extent and rate of chlorinated solvent biodegradation at the site. TSI formulated an emulsion containing soybean oil, lecithin (a soybean derivative that acts as an emulsifier), and water to provide required organic carbon. The soybean oil is broken down into smaller organic molecules and hydrogen that are then used by the dechlorinating bacteria. In the second injection event, soybean oil, a surfactant mix, a quick release substrate package, sodium bromide (a tracer), and activated carbon-treated water was used to prepare an emulsion.

Figure 2 is a schematic of the anaerobic biotreatment system showing the monitoring wells and the injection locations within the treatment cell. Injection points 1 to 7 were used in the first injection event. In this injection event, the nutrients were distributed throughout the vertical extent of the treatment area by a Geoprobe® rig at the beginning of the pilot. The Geoprobe® pushed a drivepoint to about 50 feet bgs. The drill rod was pulled back two feet to inject the fluids under pressure with a Rupe pump. The rod was then withdrawn four feet and additional fluid was injected. This process continued until about 22 ft bgs. Approximately 3,500 gallons of soybean oil emulsion containing soybean oil, soybean lecithin, and tap water (treated to remove chlorine) was injected into five points. Forty gallons of soybean oil was injected at an additional point. About 4,530 pounds of soybean oil and lecithin was injected. In addition to pressure injection of the emulsion followed by injection of chase water to disperse the nutrients, natural groundwater flow has dispersed the substrate.

During the period of February 25, 2002 to March 3, 2002, Terra Systems, Inc. constructed and utilized a low pressure injection system to inject substrate into the treatment cell with twelve injection wells (injection points 8-19). The injection system consisted of 7 one-inch wells installed to 60 ft. bgs and 5 one-inch wells installed to 55 ft. bgs. Eight of the wells were spaced 7.5 feet apart in a line. Two additional wells were placed on either side of the line. All of the wells had 20 ft. of PVC blank riser and 40 and 35 ft. of PVC screen (0.02 slot) respectively. The wells were installed using the Geoprobe™ direct-push method. Approximately 5,777 gallons of the emulsion was prepared and injected in February and April 2002. A total of 5,777 gallons of the emulsion containing 9,588 pounds of the soybean oil and surfactant mix, 94 pounds of a quick release substrate package, and 5.9 pounds of sodium bromide was injected.

4.5 Operating Parameters

The major operating parameters needed to assess the performance and cost of the bioremediation system were considered to be substrate concentrations and substrate longevity.

5.0 RESULTS

The bioremediation study at the Photocircuits Corporation site is being conducted to accelerate the degradation of the chlorinated contaminants of concern.

5.1 Performance Evaluation Criteria

The performance criteria considered in evaluating this *in situ* anaerobic bioremediation system included:

- Substrate transport and utilization in the remediation study area,
- Contaminant degradation rates and the reduction in mass of the contaminants,
- Fate of chlorinated solvent degradation compounds, and
- Levels to which contaminants can be reduced.

The evaluation data were collected by a monitoring program of nineteen field sampling events over a 79 month period.

5.2 Organization of Data

The analytical data from the treatment cell collected from each of the eighteen sampling events are summarized in the following five tables.

- Table 1 presents the volatile organic data (VOCs), final biodegradation byproducts (ethene and ethane), important electron acceptors (total iron, sulfate, nitrate, and methane), and electron donor as represented by total organic carbon (TOC).
- Table 2 converts the concentrations of the chlorinated ethenes and chlorinated ethanes to micromolar units so that one unit of PCE is equivalent to one unit of TCE, cDCE, tDCE, VC, and ethene. Similarly one unit of 1TCA is equivalent to one unit of 1DCE, 1DCA, CA, or ethane.
- Table 3 presents the field data collected in January, April, June, and October 2002; January, April, August, and December 2003; March, June, September, and December 2004; November 2006; and April 2007.
- Table 4 summarizes the changes between the samples collected within the treatment cell immediately after the oil emulsion injection and the samples collected seventy-nine months later. For wells MW-14 and MW-7, samples could not be collected in April, June, or October 2002 because of the accumulation of emulsion. Well MW-14 has been sampled since January 2003. MW-7 could not be sampled at any of these time points because of the presence of the emulsion. Positive changes indicate that the concentrations of the analyte have decreased. A negative change indicates that the concentrations have increased. In a number of cases, the contaminants were not detected in the initial samples collected after emulsion injection or in the samples

collected after fifty-nine months. In these cases, the percent change was calculated using the analyte detection limit and the percent changes are designated as greater than (>) or less than (<) the calculated change. For the downgradient wells, Table 4 summarizes the percent changes between the sample collected on 3/28/01 and the samples collected on 4/2/07 for wells MW-8, MW-12, and MW-13, for well MW-9 between 3/28/01 and 6/22/04, and between 1/22/02 and 6/22/04 for wells MW-10 and MW-11.

- Table 5 summarizes the changes in the chloroethenes, chloroethanes, electron acceptors, and electron donor for all wells from the beginning of the project in August-September 2000 to January 2002 or April 2007.

5.3 Project To Date Results

The following table summarizes the status of the key performance measures for this project as of April 2007. Details are described in subsequent sections..

Performance Measures	Values/Results
Treatment Volume:	
Soil	Approximately 92' X 157' X 60', 866,640 ft ³
Ground Water Treated:	Approximately 1,620,617 gallons
System substrate transport effectiveness:	Demonstrated distribution throughout treatment area
Substrate effectiveness:	Enhanced dechlorination
Substrate viability	Lasted for more than four years
Reduction of total contaminants of concern:	Achieved reductions of 17% to 95% except in MW-14, MW-7 (through 1/8/02), and DMP-4
Chlorinated solvent degradation product production	General decline in all contaminants with some temporary increases in degradation products, followed by reduction of the degradation products themselves by biological degradation
Waste generated	None

5.3.1 Chlorinated Ethene Results

In the monitoring wells within the treatment cell, cis-1,2-DCE, VC, and ethene were initially the predominant chlorinated ethenes with little of the parent compounds, PCE or TCE, being detected. Trans-1,2-DCE is a minor product, present at 1.1% or less of the total chlorinated ethenes. Chlorinated ethenes concentrations greater than 1,000 µg/L were initially only detected in SMP-1 and DMP-3.

Between November 2006 and April 2007, the parent compounds PCE and TCE and the intermediate daughter products cDCE, tDCE, and VC declined in well DMP-3. On a micromolar basis, VC was the dominant chlorinated ethene detected in well DMP-3 and DMP-4 in April 2007. Ethene was the dominant chlorinated ethene in April 2007 in wells MW-14, SMP-1,

DMP-1, SMP-3, and SMP-4. Well SMP-4 did not contain detectable concentrations of PCE, TCE, cDCE, tDCE, or VC in April 2007.

As previously discussed, the goal of the process is to convert PCE into ethene because the ethene is considered to be environmentally acceptable. Ethene has not been associated with long-term toxicological problems and is a natural occurring plant hormone (Sims et al 1991).

Unfortunately, given the field conditions, it is difficult to conduct a material balance. Ethene may be converted to carbon dioxide, ethane, or another product. Ethene may also be transported away with the groundwater, or production of ethene may have slowed due to some limitation on the microbial population including lack of substrate, insufficient nutrients, or lower concentrations of the parent compounds.

Ethene had been the predominant chlorinated ethene in wells MW-14, MW-7 (through 1/8/02), SMP-1, DMP-1, SMP-3, DMP-3, SMP-4, and DMP-4. In the more recent sampling events, VC, cDCE, and the parent compounds PCE and TCE have increased in several wells. The continued presence of ethene in all of the wells in the treatment area shows that complete dechlorination of the chlorinated ethenes is occurring. Low levels of acetylene, an abiotic degradation product from the reaction of PCE or TCE with ferrous sulfide and ferrous disulfide, have been detected in wells MW-14, SMP-1, and SMP-3.

The addition of soybean oil emulsion has resulted in lower concentrations of PCE, TCE, cDCE, tDCE, and VC in treatment area wells MW-14, SMP-1, DMP-1, SMP-3, DMP-3, SMP-4, and DMP-4. The most dramatic change was observed in well SMP-1 where cDCE concentrations declined from 24,900 µg/L in August 2000 to <2.0 µg/L in April 2007.

In the downgradient monitoring wells sampled since March 2001, wells MW-8, MW-10, MW-11, MW-12, and MW-13 had parent compounds PCE and/or TCE. Concentrations greater than 1,000 µg/L of chlorinated ethenes were only detected in MW-12. Total chlorinated ethenes have subsequently been greater than 1,000 µg/L in MW-13. Since March 2001, six months after the first substrate injection, TCE, cDCE, tDCE, and VC concentrations had declined in MW-12, but then cDCE, VC, and ethene concentrations rebounded between July 2005 and November 2006. The concentrations of these compounds fell between November 2006 and April 2007. The first emulsion injection appeared to have had an effect on MW-12 based upon the increases in ethene, methane, and TOC. The availability of substrate (<0.51 to 124 mg/L TOC) may be limiting the extent of dechlorination at this well. Ethene has only been detected at low levels in the other downgradient wells. The very low levels of TCE and cDCE found in MW-8 had dissipated from April 2002 to January 2003, but were detected again in from April 2003 through April 2007.

Higher levels of PCE, TCE, and cDCE have been found in the recent sampling events for MW-8. Little change in the concentrations of PCE, TCE, cDCE, or VC was noted in the deep well MW-10 between 1/22/02 and 6/22/04. Low levels of TCE and cDCE appeared in the deep well MW-11 in January 2003 and persisted through June 2004. PCE and TCE concentrations have increased in MW-13, but ethene has only been detected at low concentrations of 5.8 µg/L or less in this well. Although the area around MW-13 appeared to be substrate-limited from March 2001 until November 2002, the availability of substrate increased to between 24 and 39 mg/L from January through August 2003. In March and June 2004, TOC was found at 47 to 49 mg/L compared to < 0.51 mg/L in December 2003 and PCE, TCE, cDCE, and VC decreased over the

levels seen in December 2003. In September 2004 to April 2007, there was only 6.0 to 9.0 mg/L of TOC in MW-13 and the PCE, TCE, and cDCE concentrations have increased substantially.

In December 2003 and March, June, September, December 2004, July 2005, November 2006, and April 2007, the new recovery wells contained a mix of PCE, TCE, cDCE, tDCE, and VC with cDCE being the dominant compound. Ethene and ethane were not analyzed in these wells. Since December 2003, the total chlorinated ethenes have increased by 453% for RW-1, and 36% for RW-4 (through November 2006), but decreased by 10% for RW-2 and 63% for RW-3.

5.3.2 Chlorinated Ethane Results

The analytical data provides evidence for biodegradation of the chlorinated ethanes. Wells DMP-1, SMP-3, DMP-3, and SMP-4 had the highest concentrations of total chlorinated ethanes in September 2000 with greater than 1,000 µg/L. 1TCA was the primary chlorinated ethane contaminant in wells SMP-3 and DMP-3. Reduced products such as 1,1-dichloroethane, chloroethane, and ethane predominated in wells MW-14, MW-7, SMP-1, DMP-1, SMP-4, and DMP-4.

Well SMP-3 has shown a 96% (178,000 µg/L to 6,000 µg/L) reduction in the 1TCA concentrations. 1TCA levels in well SMP-4 have dropped by >99.97 percent. 1DCA concentrations have dropped in SMP-3 (98%), and SMP-4 (99.8%). However, increased 1DCA concentrations have been noted in MW-14, MW-7 (through 1/8/02), SMP-1, DMP-1, DMP-3, and DMP-4 as a result of the dechlorination of 1TCA. Large reductions in the 1DCE concentrations have been observed in well SMP-4 (>99.0%), but 1DCE increased in MW-14, DMP-1, and DMP-3. 1DCE was not detected in August 2000 or April 2007 in DMP-4. CA concentrations have declined by 93% in DMP-1, 29% in DMP-3, and 70% in SMP-4, but increased in other treatment cell wells excluding SMP-3 where it was not detected in November 2000.

Well SMP-4 has shown decreases in the 1TCA, 1DCA, CA, and ethane concentrations over the seventy-nine months following the first injection of the oil emulsion. There was a rebound in concentrations of these compounds between December 2000 and January 2002 in SMP-4. When substrate levels were elevated after the second application of SRSTM, the 1TCA and 1DCA concentrations dropped and have remained lower than the initial levels. In April 2007, concentrations of total chlorinated ethanes (1TCA, 1DCA, 2DCA, 1DCE, and CA) were higher than initial levels were observed in wells MW-14, MW-7 (through 1/8/02), SMP-1, DMP-1, and DMP-4. Further degradation products CA and ethane levels are elevated in wells MW-14, MW-7, SMP-1, SMP-4, and DMP-4. Chloroethane can be biodegraded under aerobic and methanogenic conditions (Lee and Davis 2000).

Concentrations of 1TCA, 1DCA, and/or CA rebounded between December 2003 and April 2007 in wells MW-14, SMP-1, DMP-1, SMP-3, DMP-3, and DMP-4. There appeared to be some TOC (20-990 mg/L), but sulfate levels increased in wells SMP-1, DMP-1, SMP-3, and DMP-3 during this period. The increase in sulfate indicates a substrate availability limitation. 1TCA, 1DCA, and CA concentrations increased substantially in well DMP-3 between June 2004 and July 2005. Concentrations of the all chlorinated ethanes declined in DMP-3 between July 2005

and April 2007. 1TCA may have been released from the soybean oil or untreated 1TCA may have been released from an upgradient location.

Relatively low levels of 1TCA and daughter products have been found in downgradient monitoring wells MW-12 and MW-13. Little of the chlorinated ethanes have been found in MW-8 or MW-9. In the deep well MW-10, concentrations of 1DCA, 2DCA, 1DCE were relatively stable between January 2002 and June 2004, and CA was detected. A low level of 1DCA was detected in MW-11 in January 2003, but not in the subsequent sample in June 2004. 1DCA concentrations have increased in MW-8 and MW-12 between July 2001 and April 2007.

The new recovery wells have relatively low levels of 1TCA with the highest concentration found in RW-1. 1DCA is the predominant chlorinated ethane with lower levels of 1DCE, traces of 2DCA, but little chloroethane except in RW-1. Between September 2004 and April 2007, concentrations of total chlorinated ethanes have increased in only one of the four recovery wells (RW-1).

5.3.3 Other Organic Compounds Results

Several other organic compounds were detected in the groundwater including acetone, methylene chloride, 2-butanone, toluene, benzene, p-ethyltoluene, 1,3,5-trimethylbenzene, 2-chlorotoluene, 4-chlorotoluene, 1,2,4-trimethylbenzene, naphthalene, o-xylene, n-propylbenzene, and methyl tert butyl ether (MTBE). Over the seventy-nine months of the project operation to date, acetone concentrations decreased by 91% in DMP-1 and 80% in MW-14, but increased in wells SMP-1, SMP-4. Methylene chloride concentrations have decreased in wells MW-7 (through 1/8/02), SMP-1, DMP-1, SMP-3, DMP-3, and SMP-4, with declines by as much as 99 percent in SMP-4, 96% in SMP-1, 95% in SMP-3, 69% in DMP-3, 47% in DMP-3, and 38% in MW-7 (through 1/8/02); increased methylene chloride concentrations have been observed in MW-14 and DMP-4.. Methylene chloride can also be anaerobically degraded. Toluene concentrations have declined in six of the eight wells in the project area. Although toluene can be also degraded anaerobically, the addition of soybean oil may have little effect on its biodegradation of toluene as dechlorinators are probably not involved in the biotransformation of toluene. 2-Chlorotoluene concentrations declined by 98% in SMP-4, 83% in DMP-4, <82% in SMP-1, <29% in DMP-3, and 24% in DMP-1, but increased in MW-7 (through 1/8/02). 2-Chlorotoluene may be biodegraded to toluene and potentially further under anaerobic conditions. MTBE was first detected at 9.0 µg/L in SMP-3 in July 2001. MTBE was found at levels up to 125 µg/L in DMP-3, SMP-1, SMP-3, and DMP-4 in January 2002. We are speculating that the MTBE plume is from an off-site source since it was not used on the Photocircuits site. MTBE has not been detected in any monitoring well since July 2002. The MTBE appears to have flushed through the system. In April 2007, other potential components of gasoline or other petroleum fuels including benzene, toluene, o-xylene, 1,2,4-trimethyl benzene, 1,3,5-trimethyl benzene, and/or naphthalene were detected in wells MW-14, SMP-1, DMP-1, SMP-3, DMP-3, SMP-4, DMP-4, MW-13, and RW-1, but not wells MW-8, MW-12, RW-2, RW-3, or RW-4 (November 2006).

Few of the contaminants other than the chlorinated ethenes, chlorinated ethanes, and fuel aromatics were found in the downgradient wells. 2-Chlorotoluene concentrations have increased by 180% in MW-12 between 3/28/01 and 4/2/07 and also have increased in RW-1. 4-Chlorotoluene has been found in MW-12.

In December 2003 through April 2007, the recovery wells contained the following compounds: PCE, TCE, cDCE, VC, ITCA, IDCA, 1DCE, CA, methylene chloride, toluene, and 2-chlorotoluene.

5.3.4 Sum of VOAs

The sum of the concentrations of all of the contaminants in each well was calculated excluding the final degradation endproduct gases: acetylene, ethene, and ethane. The sum of the VOAs has declined by up to 96% in SMP-3 with large decreases in SMP-4 (95%), SMP-1 (88%), DMP-1 (30%), and DMP-3 (17%). The sum of VOAs has increased by 1,805% in MW-14 as the contaminated groundwater displaced during injection came back into the well and potentially as VOCs adsorbed into the oil were released. Increases in the sum of VOAs were also observed to a lesser degree in MW-7 (33 through 1/8/02) and DMP-4 (125%). The overall average of the sum of the volatiles has declined by 79.8% over the course of the pilot and full scale /implementation. This average includes the seven wells sampled on 4/2/07 and the well (MW-7) last sampled on 1/8/02. The average percent removal was lower in April 2007 than in the previous sampling round in November 2006 as total volatiles increased in MW-14, SMP-1, and DMP-1.

Since 3/28/01, the total volatiles in the downgradient wells outside of the influence of the substrate injection have fallen in MW-10 (43%), MW-11 (<73%), and MW-12 (28%), but increased in MW-8 (4,750%) and MW-13 (273%) and have remained non-detect in MW-9. The highest concentrations of total VOAs in the recovery wells in the first round of samples in December 2003 were found in well RW-1 (3,680 µg/L) followed by RW-2 (1,693 µg/L), RW-3 (1,237 µg/L), and RW-4 (649 µg/L). The total volatiles through April 2007 have increased by 561% in RW-2 and 40% in RW-4 (through 11/7/07), but decreased in RW-2 (26%) and RW-3 (65%).

5.3.5 Substrate Distribution

The total organic carbon concentrations in April 2007 within the treatment cell ranged from 22 mg/L in DMP-3 to 620 mg/L in MW-14. Well MW-7 contained the emulsion in April 2007 and was not sampled. It presumably contains very high levels of TOC. TOC levels were below the target level of 50 mg/L in wells SMP-1, DMP-1, DMP-3, SMP-4, and DMP-4 in April 2007. A substrate level of 50 mg/L TOC should provide sufficient carbon to support dechlorination and other electron accepting processes such as methanogenesis and sulfate-reduction.

The soybean oil is degraded from long chain fatty acids such as palmitic, stearic, linoleic, and linolenic acids to shorter fatty acids including propionic, butyric, formic, and acetic acids. As the fatty acids are broken down, hydrogen and acetic acid are released. The hydrogen is used for reductive dechlorination and other electron accepting processes including nitrate-reduction, sulfate-reduction, iron-reduction, and methane formation. While there appears to be plenty of TOC available within the treatment cell, it may not be in a form that supports rapid dechlorination and the removal of the competing electron acceptors. TSI recommends that samples be collected and analyzed for volatile fatty acids from MW-14 and SMP-3 which have high levels of TOC and sulfate. Additional substrate injection will most likely be required to overcome this potential limitation.

The substrate injections have previously impacted TOC levels only in wells MW-12 and MW-13 of the downgradient wells. Downgradient wells MW-8, MW-9, MW-10, MW-11, MW-12, and MW-13 now appear to be substrate-limited. Based upon the limited reduction dechlorination of chlorinated ethenes and ethanes, the recovery wells RW-1, RW-2, RW-3, and RW-4 also appear to be in areas that are substrate-limited.

5.3.5 Electron Acceptor Results

As the microbes break down the emulsion, nitrate and sulfate would be depleted and the concentrations of iron and methane would increase. Nitrate-nitrogen was detected in April 2007 in the treatment cell at concentrations between 0.085 and 2.03 mg/L and is a minor electron acceptor. Nitrate was detected in downgradient wells MW-8 and MW-13 in April 2007 at concentrations of 0.054 (MW-12) to 7.7 mg/L (MW-8). The predominant electron acceptor in the groundwater within the treatment cell in April 2007 was sulfate with concentrations that ranged from 17 mg/L in MW-14 to 911 mg/L in DMP-1. Sulfate concentrations have declined from the initial concentrations in September 2000 in wells MW-14 (99.7%), DMP-1 (96.9% from 29,600 to 911 mg/L), SMP-4 (99.9%), SMP-3 (31%), and DMP-4 (26%) as would be expected with consumption of the oil emulsion. Sulfate levels increased in MW-7 (through 1/8/02), SMP-1 (87%), and DMP-3 (451%). The average sulfate concentration in the cell has declined by 91%. However, sulfate levels increased in wells SMP-1, DMP-3, SMP-4, and DMP-4 between November 2006 and April 2007. Total iron concentrations within the treatment cell in April 2007 ranged from 11 mg/L in SMP-3 to 28.9 mg/L in SMP-1, which indicated that iron is also an important electron acceptor. Over the seventy-nine month project, total iron concentrations have decreased in six of the eight wells in the study area. The drop in dissolved iron concentrations in the other wells may be due to precipitation of the ferrous iron with sulfide produced from the utilization of sulfate. During the most recent sampling event in April 2007, methanogenic conditions ($>1,000 \mu\text{g/L}$ methane) were detected in all test cell wells. Methane concentrations have increased in the downgradient monitoring wells MW-12 and MW-13 in the project area between September 2000 and April 2007.

Well MW-8 is under aerobic conditions based upon the presence of dissolved oxygen, nitrate, and sulfate, and the low levels of iron and methane. This well is largely uncontaminated. While MW-9 has little organic contamination, it appears to have been impacted by the biodegradation processes upgradient as it has elevated iron and methane levels and decreased sulfate levels. No electron acceptor data was available for wells MW-10, MW-11, and the new recovery wells. Wells MW-12 and MW-13 are under sulfate to methanogenic conditions based upon the elevated sulfate and methane levels.

5.3.6 Field Parameters

Field parameters including water level, pH, temperature, specific conductivity, redox potential, dissolved oxygen, and bromide (a tracer added with the emulsion) were collected since January 2002 for wells SMP-1, DMP-1, SMP-3, DMP-3, SMP-4, and DMP-4. Field parameters were collected for downgradient wells MW-8, MW-9, MW-12, and MW-13 since the April 2002 sampling event. The water levels ranged between 6.42 feet (SMP-1) to 7.96 feet (MW-8) below the top of the casing for wells in January 2002.

The pH was generally neutral, between 6.3 and 7.8. Well SMP-3 had an elevated pH reading, 8.7-9.9 from 1/02 to 1/03, but declined to between 6.4 and 7.6 from January 2003 to April 2007. The pH dropped to slightly acidic conditions of 5.3-6.5 in SMP-4 from 7/02 to 9/04. Downgradient wells MW-12 and MW-13 were slightly acidic to neutral, 6.2 to 7.3. The pH in the downgradient well MW-8 ranged from slightly acidic, 6.4 to slightly basic, 8.7.

Groundwater temperatures ranged between 10.3 to 25.9 °C. In general, the specific conductivity of the groundwater within the treatment cell was high, between 6 and 5,890 umhos/cm. Downgradient wells MW-8 and MW-9 had lower specific conductivity readings of 120 to 493 umhos/cm. Downgradient wells MW-12 and MW-13 had higher specific conductivity levels than MW-8 and MW-9.

Negative redox potentials of -137 (SMP-4) to -17 mV (SMP-3) were found in the wells within the treatment cell in April 2007. Downgradient wells MW-8 and MW-13 had positive redox potentials in April 2007.

Dissolved oxygen readings ranged from 0.1 to 9.1 mg/L in April 2007. The high dissolved oxygen levels found in SMP-1, DMP-1, SMP-3, DMP-3, SMP-4, and DMP-4 are not consistent with the low redox potentials and anaerobic conditions found in these wells.

Bromide was injected with the emulsion. Wells SMP-1, DMP-1, SMP-3, DMP-3, SMP-4, and DMP-4 had bromide levels of greater than 10 mg/L in June 2002. These wells generally had elevated TOC levels. Bromide levels increased between April and June 2002 in all monitoring wells within the cell except DMP-4. The highest bromide levels were in wells DMP-1, DMP-3, and SMP-4. Wells DMP-3 and SMP-4 had high TOC concentrations. Bromide was not measured after July 2002.

6.0 DISCUSSION

Previous studies have demonstrated the anaerobic dechlorination of PCE using aquifer solids and water in the laboratory (Parsons et al. 1985, Scholz-Muramatsu et al. 1995, and DiStefano et al. 1991). Previous field studies have also demonstrated the anaerobic dechlorination of PCE (Beeman et al. 1994, Ellis et al. 2000). Therefore, microbial reductive dehalogenation is a potential remedial mechanism for halogenated compounds in groundwater aquifers.

The objective of the technology is to convert PCE and 1TCA into ethene and ethane. The produced ethene is considered to be environmentally acceptable, because ethene has not been associated with long-term toxicological problems and is a natural occurring plant hormone (Sims et al. 1991). Furthermore, ethene is known to further biodegrade to carbon dioxide under aerobic environmental conditions (Beeman et al 1994).

VC has been thought to persist in anaerobic environments and to be more toxic to bacteria than the parent compounds (Barrio-Lage et al. 1991). However, subsequent work has clearly established that VC is biodegraded to ethene and ethane. The pattern of increase and disappearance of cDCE and VC is suggestive of microbial succession.

Conditions continue to be favorable for accelerated anaerobic biodegradation of the chlorinated solvents at the Photocircuits site based upon the following positive results from the treatment cell to date including:

- decreases in the parent compound concentrations observed in many wells, particularly the large drops in the 1TCA and 1DCA concentrations in wells SMP-3 and DMP-3
- increases in the daughter products including final products ethene and ethane in many of the wells.
- good distribution of substrate and its consumption
- prevalence of reducing conditions based upon the removal of sulfate and the production of dissolved iron and methane

During the treatment period of 79 months, we have successfully demonstrated that the addition of a food grade carbon source will enhance the extent and rate of chlorinated solvent biodegradation at this site as indicated by the following observations:

- Total contaminant concentrations have decreased by an average 79.8%.
- The average concentrations of the parent compound 1,1,1-trichloroethane has decreased by 89%.
- Ethene was the dominant chlorinated ethene in wells MW-14, SMP-1, DMP-1, SMP-3, and SMP-4 in April 2007.
- Three monitoring wells (MW-7, MW-14, and DMP-4) have shown increased total volatile concentrations since September 1, 2000 by 33 to 1,805%. Well MW-7 could not be sampled since January 2002 due to the presence of emulsion and the percent change calculations are from September 2000 to January 2002. However, when viewed over the last 13 years, the total VOC concentrations in MW-7 have decreased 96%. From 11/99 to 4/07, total VOC concentrations decreased by 77% in MW-14. Since first monitored in May 1999, well DMP-

3 has shown a decrease in total volatiles from 60,390 to 26,654 µg/L primarily due to decrease in 1TCA and 1DCA concentrations.

This project was originally undertaken for the purpose of degrading the contaminant source, and it has been successful in that regard. We are now turning our attention to the degradation of the residual 10-20% of the contaminant mass. We anticipate that the rate of degradation (as a percentage of the total) will slow somewhat as contaminant concentrations continue to drop through the part per billion (ppb) range due to natural processes such as molecular diffusion. However, as long as substrate is available at the necessary levels and subsurface conditions are not materially altered, contaminant degradation will continue until the contaminants are consumed. Injection of additional substrate is recommended.

7.0 CONCLUSIONS

Although the study is an on-going program, there is now sufficient data to facilitate a comparison of the project to date results with the project's objectives. The following summary presents the project objectives in bold with the results.

Determine if the addition of a food grade carbon source will enhance the extent and rate of chlorinated solvent biodegradation at the site.

The overall average of the sum of the volatiles has declined by 80% over the course of 79 months. Increases in intermediate and final daughter products from the chlorinated ethenes and ethanes have been observed in all of the primary monitoring wells.

Determine if the food grade carbon source can be adequately distributed in the formation such that the microorganisms can utilize it.

TOC levels in excess of 50 mg/L were established in all eight of the primary monitoring wells in the study area. The TOC levels after system start up ranged from 39 mg/L to 23,500 mg/L. TOC levels declined from the beginning of the treatment in most wells as the emulsified oil was utilized. TOC levels rose in all wells in the treatment cell after the second injection of the emulsion and ranged from 132 to 1,360 mg/L in August 2003. Another injection of the emulsified soybean oil is recommended to promote more complete dechlorination and to consume the competing electron acceptors. Although it is not possible to do a mass balance because of site conditions, evidence of primary contaminant reduction combined with increases in intermediate and final daughter products strongly suggests that the TOC decreases are a result of biological utilization.

Determine what role bioremediation has in the overall remediation strategy for the site.

Based on the results to date, it appears that bioremediation can cost effectively destroy the contaminants in an acceptable time frame. As a consequence, it appears that bioremediation will be the primary treatment technology for contaminant destruction at this site.

Table 5. Summary of Changes in Concentrations of Chloroethenes, Chloroethanes, Electron Acceptors, and Electron Donor by Well

Well	Chlorinated Ethene Dechlorination	Chlorinated Ethane Dechlorination	Electron Acceptors	Electron Donor Availability
MW-14	Little PCE, TCE, cDCE, or VC found initially. Ethene moderate. Low levels of PCE, between 11.06 and 4.07. Ethane fairly stable, but low.	1TCA, 1DCA, 1DCE, and CA increased	Low nitrate found in 4.07. Sulfate decreased by 99.7%. Methane up greatly. Iron increased from 12.00 to 12.03, but is now similar to initial levels	Emulsion found 4.02, 6.02, and 10.02 and TOC levels had been above 1,000 mg/L. TOC availability was lower in 1.03 and 3.04, but returned to ~600 mg/L in 6.04 through 4.07.
MW-7	Ethene generally predominant product, TCE up slightly, cDCE and VC down by 82 and 73% from start of pilot. 1DCE up slightly. Not sampled since 1.02 because of emulsion in well.	1DCA and CA up. CA major product. Ethane produced.	Sulfate increased from 69 to 949 mg/L from 7.01 to 1.02, methane and iron up greatly	TOC had fallen to 17 mg/L in 1.02. Emulsion found thereafter.
SMP-1	TCE and cDCE up beginning in 1.02, but fell between 7.02 and 10.02 after emulsion injection and were low or not detected from 1.03 through 4.07. VC increased and then fell to non-detect as more substrate became available. VC found in 12/03, 6/04, 7/05, 11/06, and 4/07, but not 3/04, 9/04, or 12/04. Ethene increased when substrate levels were higher, but declined beginning in 8/03. Ethene has been primary chlorinated ethene since 10/02.	No 1TCA detected from 7.01 to 12/04. 1TCA, 1DCA, and CA have increased since 9/04. 1DCE not detected from 10.02 to 7.05, found 11.06 and 4/07. CA produced and is primary chlorinated ethane. Little ethane.	Nitrate low in 4.07. Sulfate increased 87% from start of pilot. Iron up by 46%, and methane up by 400% from start of pilot.	TOC rebounded to 1,280 mg/L in 4.03; enhanced dechlorination. TOC dropped to 50 mg/L in 12.03 and 3.04, rebounded to 398 mg/L in 6/04, but was only 34 to 64 mg/L in 9/04 to 4.07. Based upon increases in competing electron acceptor sulfate, decreases in iron, and increases in 1DCA and CA, area thought to be substrate-limited
DMP-1	Only trace PCE found in 4.07. VC has decreased by 37% over course of pilot, but rebounded between 12/04 and 4/07. Ethene remains predominant product.	1TCA up ~1,218,082%, 1DCA up 793%, 1DCE up 9,138%, CA down by 93%, little ethane detected. Substantial increase in 1TCA and 1DCA over last 28 months with low substrate levels.	Over the course of the pilot, sulfate down 97% and iron by 93%, and methane increased by 46%. Since 12.03, sulfate has increased from 226 to 911 mg/L suggesting substrate-limitation.	TOC increased from 24 mg/L in 6/02 to 284 mg/L in 4.03, but declined after that sampling event. Inadequate supply since 9/04.
SMP-3	TCE and cDCE not detected since 7.05, and VC has decreased. VC and ethene predominant products.	1TCA down by 96%, 1DCA down 98%, 1DCE down by ~55%, and CA decreased by ~85%. 1TCA and 1DCA decreased between 7.05 and 4/07. Some ethane.	Sulfate decreased from 3,640 mg/L in 4.02 to 75 mg/L in 4/03, but increased to 2,570 mg/L in 6/04 indicating potential substrate limitation. Lower levels of 124 to 472 mg/L found in 9/04 to 4/07. Iron down by 78%, but methane increased by 6,300%.	TOC in 4.02 up to 1,600 mg/L, but then fell below optimal levels. Adequate levels since then except 12.03 (~51 mg/L), 12.04 (49.5 mg/L), and 11.06 (49 mg/L).
DMP-3	No detectable PCE, TCE, and cDCE in 4.07. VC greater than ethene from 7.20/05 to 4/07. Substrate limited.	1TCA down by 68%, 1DCA up by 168%, and 1DCE up by 797%. CA decreased by 29%. Ethane down. 1TCA and 1DCA increased greatly between 3/04 and 4/07 due to substrate limitation.	Sulfate increased by 45.1% over pilot with increased levels from 9/04 to 4/07. Methane up, but iron decreasing.	TOC increased to 349 mg/L after second emulsion injection, but has fallen below target to 19 mg/L in 12.03. Elevated TOC of 230-243 mg/L found in 3/04 to 6/04, but fell to ~50 mg/L in 9/04 to 4/07. Well substrate-limited

Table 5 continued. Summary of Changes in Concentrations of Chloroethenes, Chloroethanes, Electron Acceptors, and Electron Donor by Well

Well	Chlorinated Ethene Dechlorination	Chlorinated Ethane Dechlorination	Electron Acceptors	Electron Donor Availability
SMP-4	PCE, TCE, cDCE, tDCE, and VC not detected 4/07. Ethene again predominant chlorinated ethene.	1TCA, IDCA, and 1DCE down by >99 to >99.9%. CA up sharply between 12/04 and 11/06, but lower in 4/07. Little ethene.	Sulfate decreased to <1.5 mg/L in 6/04 to 7/05, but increased to 87 mg/L in 14/07. Iron has decreased by 80%, and methane increased greatly.	High levels of TOC (3,680 mg/L found on 10/03) and were elevated until 12/03 when only <0.51 mg/L found. Adequate TOC of 53 to 341 mg/L found in 3/04 to 4/07.
DMP-4	No detectable PCE, TCE, cDCE, or tDCE in 4/07; elevated VC, and lower ethene.	1TCA down 64%, 1DCA up by 7644% and 1DCP non-detect 14/07. CA increased greatly between 12/04 and 11/06, but lower in 4/07. Little ethene.	Sulfate down 26%, iron down 62%, and methane increased.	TOC adequate levels (>50 mg/L) from 3/04 through 11/06, but only 27 mg/L in 4/07. Increases in 1DCA, and CA suggest substrate limiting.
MW-8	PCE, TCE, and cDCE detected 4/07. No VC or ethene.	1DCA and 1DCE detected in 4/07.	Sulfate decreased by 10% and iron has increased by 74%.	Little TOC available.
MW-9	No chlorinated ethenes detected in 6/04.	No chlorinated ethanes detected in 6/04.	Low sulfate, some methane and iron.	Little TOC available at last sampling point in 7/01.
MW-10	PCE, TCE, and cDCE detected in 6/04, but no VC.	1DCA, 2DCA, 1DCA, and CA detected in 6/04.	Not available	Based upon contaminant distribution, likely to be substrate-limited.
MW-11	Low levels of TCE and cDCE detected in 6/04, but no VC.	No chlorinated ethanes detected in 6/04.	Not available.	Based upon contaminant distribution, likely to be substrate-limited.
MW-12	TCE, cDCE, and tDCE are decreasing, and VC increasing. Ethene lower in 4/07 than 11/06.	1DCA increased 52%, 1DCE up >19%, and ethane detected at moderate levels. CA not detected 7/03 to 4/07.	Sulfate decreased by 34%, iron increased by 74%, and methane increased by 590%.	TOC level adequate in 6/04, 124 mg/L, but decreased to 34 mg/L or less in 9/04 to 4/07.
MW-13	Increases in PCE, TCE, cDCE, and VC concentrations from 12/03 through 4/07. Some ethene detected.	Increases in 1TCA (225%), 1DCE (148%), and CA (>10,900%), but decreased 1DCA (1%), and ethane (78%) concentrations.	Methane increased, but iron down by 8%, and sulfate down 57%.	TOC level of 6-9 mg/L in 12/04 to 4/07, well below optimal.
RW-1	cDCE major product with elevated TCE and lower VC and PCE. Concentrations of PCE increased by 562% and TCE by 4483%, cDCE by -236%, and VC by -204% between 12/03 and 4/07. No ethene data.	1DCA primary chlorinated ethane, some 1TCA, 1DCE, and CA. 1TCA, 1DCE, 1DCA, CA, and 1DCE increased by 194% to 775% between 12/03 and 14/07.	Not available.	Based upon contaminant distribution, likely to be substrate-limited.
RW-2	cDCE major product with some VC, PCE, TCE, and occasional 1DCE. No ethene data. From 12/03 to 4/07, total chlorinated ethenes have remained relatively stable.	1DCA and 1DCE primary chlorinated ethanes. Not available, but no detectable 1TCA or CA. Total chlorinated ethanes have remained stable.	Not available.	Based upon contaminant distribution, likely to be substrate-limited.
RW-3	cDCE major product with moderate TCE, and limited VC, PCE, and tDCE. No ethene data. From 12/03 to 4/07, total chlorinated ethenes decreased by 63%.	1DCA and 1DCE primary chlorinated ethanes. Not available, with no detectable 1TCA or CA. From 12/03 to 4/07, total chlorinated ethanes decreased by 62%.	Not available.	Based upon contaminant distribution, likely to be substrate-limited.
RW-4	cDCE major product with moderate TCE, and low levels of PCE and tDCE and VC. No ethene data. From 12/03 to 11/06 (no data for 4/07), total chlorinated ethenes increased by	1DCA and 1DCE primary chlorinated ethanes. Not available, but no detectable 1TCA or CA. Total chlorinated ethanes decreased by 47% from 12/03 to 11/06.	Not available.	Based upon contaminant distribution, likely to be substrate-limited.
