1.0 INTRODUCTION

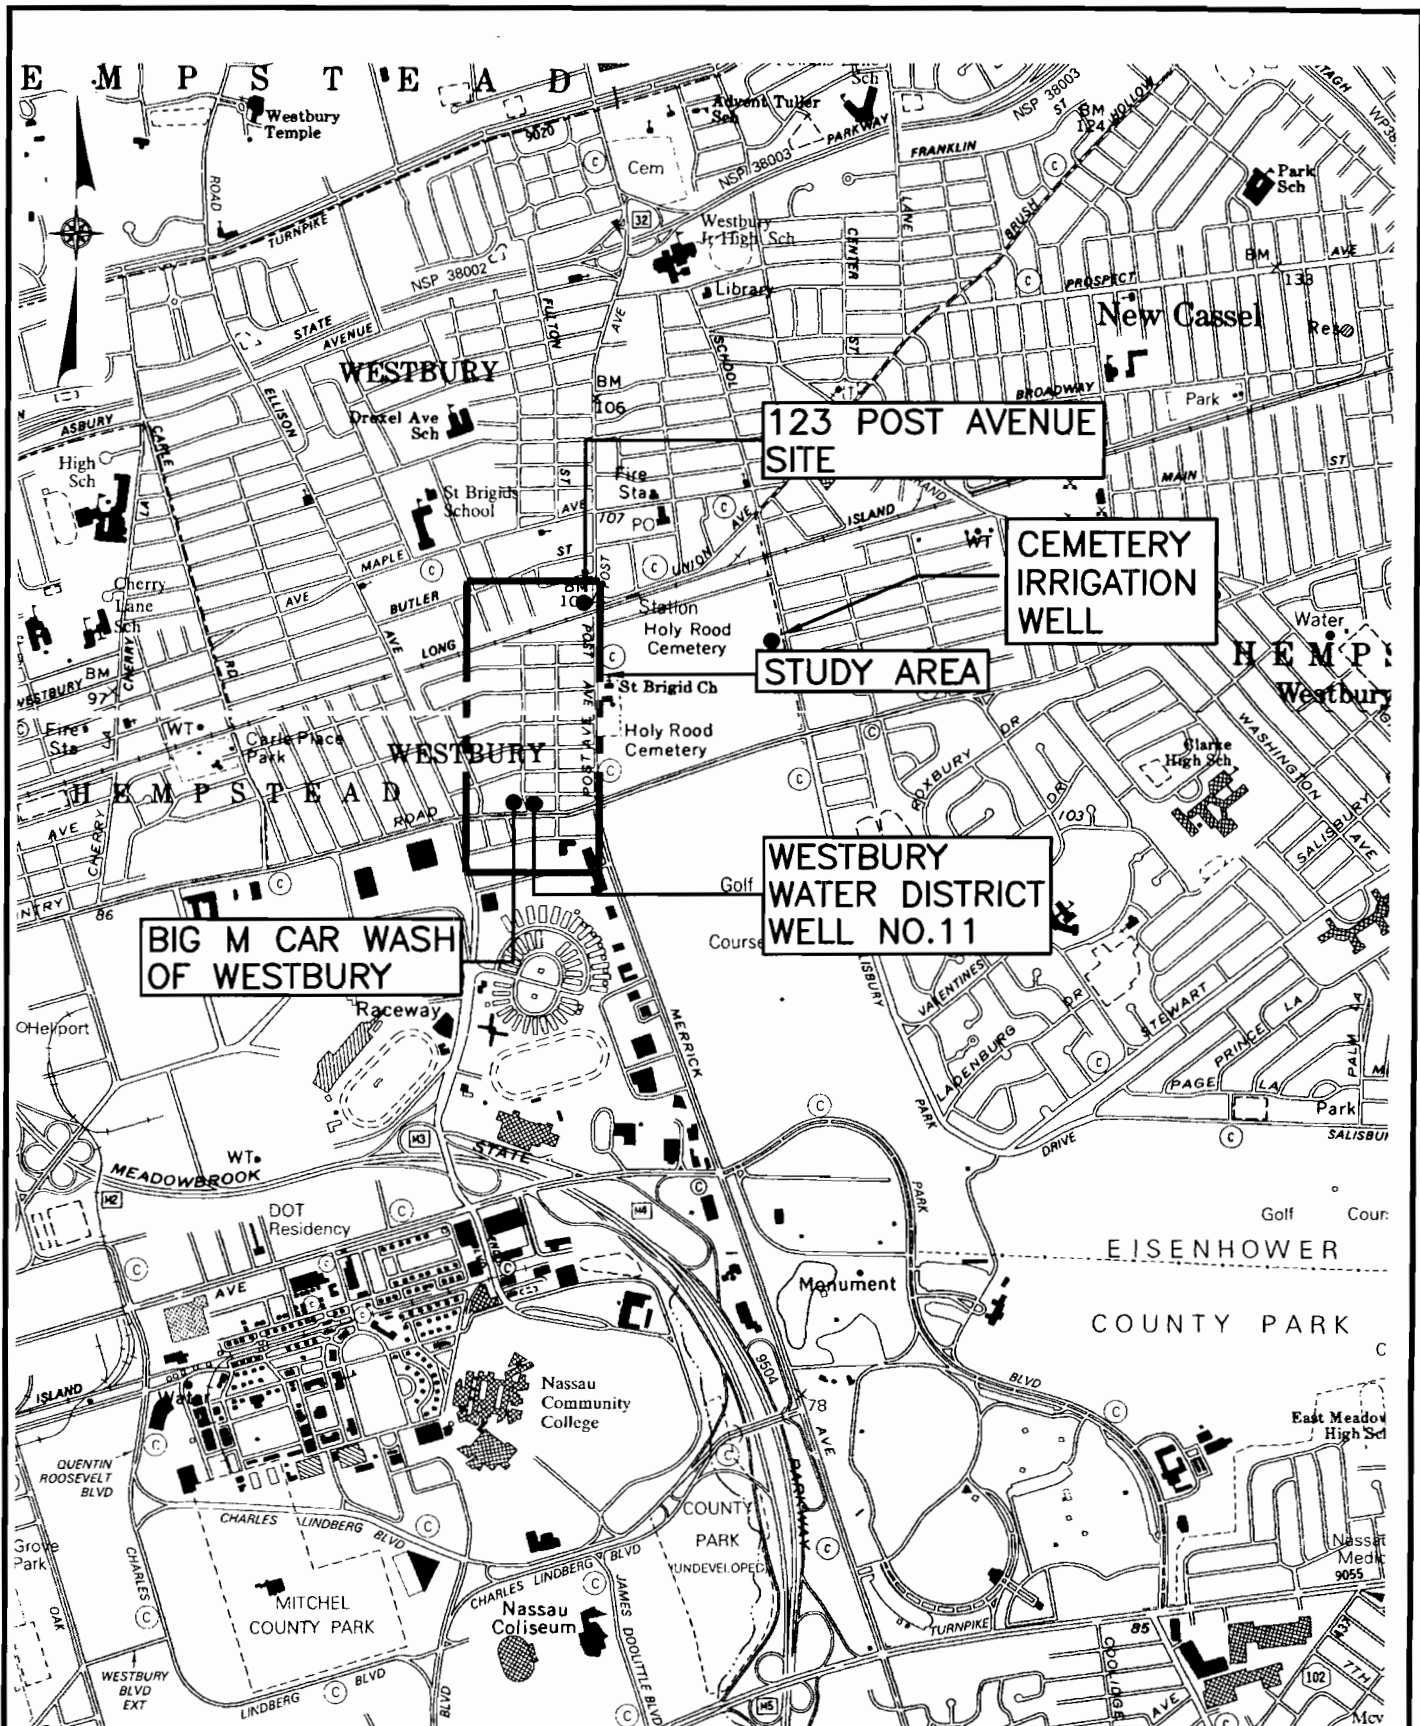

As part of New York State's program to investigate and remediate hazardous waste sites, the New York State Department of Environmental Conservation (NYSDEC) issued Work Assignment D003600-23 to Dvirka and Bartilucci Consulting Engineers (D&B) of Woodbury, New York, under its Superfund Standby Contract, to conduct a Remedial Investigation (RI) and Feasibility Study (FS) to evaluate groundwater quality downgradient of an active dry cleaning facility located at 123 Post Avenue in the Village of Westbury, Nassau County, New York. The off-site groundwater investigation is being conducted as Operable Unit 2 (OU2) of the site RI/FS with funds allocated under the New York State Superfund Program. This document presents the results of the OU2 Remedial Investigation. Investigation of soil and groundwater contamination at the 123 Post Avenue Site is being conducted by the property owner as Operable Unit 1 of the Remedial Investigation.

This report was prepared, and the activities performed as part of the RI, were conducted in accordance with the federal Comprehensive Emergency Response, Compensation and Liability Act (CERCLA); Superfund Amendments and Reauthorization Act (SARA); and the New York State Superfund Program.

1.1 Project Objectives

The purpose of the OU2 RI was to evaluate and characterize groundwater quality off-site and downgradient of the 123 Post Avenue Site to determine the extent of off-site contamination, whether potential impacts to human health exist, and if remediation of off-site groundwater contamination is warranted. A primary focus of the investigation was to evaluate whether the site is a contributing source for the trace levels of trichloroethene (TCE) and 1,2-dichloroethene (1,2-DCE) that recently have been detected in Westbury Water District Well No. 11 (NYSDEC designation N-5654). TCE and 1,2-DCE are both breakdown products of tetrachloroethene (PCE), which is a common dry cleaning solvent. Well No. 11 is located approximately 2,000 feet south-southwest/downgradient of the site.

FIGURE 1-1

F:118601860-1A.dwg, 02/07/02 09:50:44 AM, AKiffin

The mean annual temperature for the period from 1949 through 2000, as measured at Brookhaven National Laboratory, ranged from 47.5°F in 1967 to 53.1°F in 1998, with an average of 50.0°F. During 2000, the mean temperature was 50.6°F.

1.2.3 Topography

The topography in the vicinity of the study area is relatively flat. Elevations range from approximately 100 to 105 feet mean sea level. The only distinct topographic feature within a mile of the study area is a moderate valley trending south-southeast in the eastern portion of the study area. Post Avenue and Merrick Avenue (south of Old Country Road) are located within this low area. The elevation of this topographic low is approximately 15 feet lower than the higher area to the west of these streets.

1.2.4 Water Supply and Sewers

The study area is served by public water. The Westbury Water District Well No. 11 is located at the intersection of South Grand Street and Myrtle Avenue, approximately 2,000 feet south of the dry cleaning facility. Well No. 11 is screened in the Magothy aquifer from 474 to 535 feet below ground surface and yields approximately 2,000,000 gallons per day (1,400 gallons per minute). Currently, the water pumped from this well is not treated prior to distribution.

In addition to Well No. 11, there is also a water supply well at the Big M Car Wash of Westbury, located directly west of Well No. 11 on South Grand Street (see Figure 1-1). This well is screened from 54 to 64 feet below ground surface and has a maximum yield of approximately 37 gallons per minute. The water from this well is used for car washing only. Potable water for the car wash facility is supplied by the Westbury Water District.

The study area is served by public sanitary and storm sewer systems. Sanitary sewage is treated at the Nassau County Department of Public Works Cedar Creek Water Pollution Control Plant. Storm water flows from catch basins in the streets into a large diameter pipe which runs

beneath Post Avenue. The discharge point for the storm water is a recharge basin several miles south of the study area.

1.3 Site History and Previous Investigations

NYSDEC and Nassau County Department of Health files (NCDH) were reviewed to determine the site history and previous investigations conducted in the study area.

1.3.1 Site History

The building at the site was constructed in 1949 with at least one expansion in 1957. The building has been occupied by a dry cleaner since at least 1957. The building was connected to the municipal sanitary sewer system in 1979 or 1980. Prior to this time, wastewater generated on-site were apparently discharged to an on-site sanitary system.

1.3.2 Previous On-site Investigations

Periodic inspections of the site have been conducted by the NCDH since at least 1985. In July 1995, a NCDH inspection revealed the presence of two floor drains in the western portion of the building. One floor drain was located in the building's boiler room and the other was located in the workroom near the dry cleaning machine. Due to the presence of the floor drains, the site was referred to the United States Environmental Protection Agency (USEPA) for action under the Underground Injection Control (UIC) program.

In December 1997, the NYSDEC issued a Notice of Intent to Designate a Potential Hazardous Waste Disposal Site for the site. In June 1998, the USEPA approved a UIC Closure Plan for the floor drains in the on-site building. In July 1998, it was revealed to the NCDH by the consultant for the property owner that soil samples had been collected from the two floor drains in January 1996. At that time, soil samples from the floor drain in the boiler room contained PCE at concentrations up to 18,000 micrograms per kilogram (ug/kg) and TCE at

concentrations up to 100 ug/kg. Soil samples from the workroom floor drain contained PCE at concentrations up to 5,800,000 ug/kg and TCE at concentrations up to 40,000 ug/kg.

In August 1998, soils were excavated from beneath each of the floor drains. Clean endpoint samples were collected from the boiler room floor drain. Endpoint samples collected from the workroom floor drain contained PCE at concentrations up to 220,000 ug/kg. Since additional soil removal could not be conducted due to concerns about undermining the building foundation, soil vapor extraction was recommended for remediation of the remaining soil contamination. Ten drums (7,000 pounds) of PCE-contaminated soil from the floor drains were transported for off-site disposal as hazardous waste in October 1998. Based on these results, the site was placed on the New York State Registry of Inactive Hazardous Waste Sites in December 1998.

In February 1999, the USEPA approved a source area investigation for the site to evaluate groundwater contamination from the floor drains. As part of this investigation, one monitoring well (MW-1) was constructed at the upgradient boundary of the site and two monitoring wells (MW-2 and MW-3) were constructed between the on-site building and the LIRR tracks in March 1999. PCE was detected in the upgradient well at a concentration of 95 micrograms per liter (ug/l) and in the downgradient wells at concentrations up to 20,000 ug/l. The USEPA response to the June 1999 report describing the groundwater sample results recommended additional on-site investigation, but did not address the need for off-site investigation.

In March 1999, a soil boring was constructed through the workroom floor drain to evaluate the vertical distribution of the detected contamination. PCE was found in each sample collected. The maximum PCE concentration detected was 270,000 ug/kg at 10 to 11 feet below ground surface (bgs). PCE concentrations decreased with depth to the water table (53 ug/kg at 20 to 22 feet bgs and 17 ug/kg at 30 to 32 feet bgs), and increased slightly just below the water table (62 ug/kg at 36 to 40 feet bgs).

In August 2000, a revised work plan for additional investigation at the site was submitted to the NYSDEC. Activities to be conducted under this work plan included collection of soil/sediment samples from the former on-site septic system, collection of groundwater samples, including vertical profiling, and performance of a pilot study for an on-site soil and groundwater remediation system utilizing air sparging and soil vapor extraction (SVE). As part of that investigation, four soil borings were constructed immediately east of the on-site building. These borings were reportedly located in the vicinity of the former sanitary system, although the source of the information regarding the system's location was not reported. Two or three soil samples from each boring were collected for laboratory analysis. According to the report, the samples with the highest headspace readings, or the samples immediately above the water table, were analyzed. PCE, TCE and 1,2-DCE were not detected in any of the soil samples. The only compound that was detected at a concentration above NYSDEC Recommended Soil Cleanup Objectives (RSCO) was acetone, which was detected in one sample at 210 ug/kg. The RSCO for acetone is 200 ug/kg. On-site sample locations are shown on Figure 1-2.

Groundwater samples were collected from the three existing shallow (water table) monitoring wells on-site and three direct push vertical profile borings located between the southern wall of the dry cleaner building and the LIRR tracks. Three samples were collected from each vertical profile boring, at the approximate water table (depth of 36 to 40 feet or 40 to 44 feet below ground surface) and at depths of 56 to 60 feet and 76 to 80 feet below ground surface. PCE was detected in each of the nine vertical profile groundwater samples at concentrations ranging from 4 ug/l to 3,700 ug/l. At each location, the PCE concentration was greatest in the shallowest sample (16 ug/l to 3,700 ug/l) and decreased significantly with depth. PCE concentrations were highest at the location along the middle of the building's southern wall (3,700 ug/l to 23 ug/l) and lower at the southeastern and southwestern corners of the building (16 ug/l to 4 ug/l and 64 ug/l to 4 ug/l, respectively). TCE and 1,2-DCE were only detected in the deepest sample collected at the northwestern corner of the building, at concentrations of 4 ug/l and 8 ug/l, respectively.

PCE was also detected in each of the monitoring wells samples. The two wells located south (downgradient) of the building (MW-2 and MW-3) contained PCE at concentrations of

ON-SITE SAMPLE LOCATIONS

FIGURE 1-2

5,800 ug/l and 16,000 ug/l, respectively. These wells are both located in the western portion of the area between the dry cleaner building and the LIRR tracks. MW-1, located adjacent to the northeastern corner of the building, contained PCE at 1,200 ug/l. Neither TCE nor 1,2-DCE were detected in any of the monitoring well samples.

A 4-well SVE system has been operating at the site since May 2001. A work plan for design of the air sparging system currently is being prepared.

1.3.3 Previous Off-site Investigations

In 1997, a property transfer investigation was conducted at 117 Post Avenue, immediately south of the LIRR tracks that form the southern boundary of the site. As part of this investigation, seven monitoring wells were constructed in two phases. Shallow groundwater samples from these wells contained elevated concentrations of volatile organic compounds (VOCs), primarily PCE, which was detected in each well at concentrations ranging from 9.6 ug/l to 15,000 ug/l. TCE was detected in five of the seven wells at concentrations ranging from 0.52 ug/l to 110 ug/l. The report prepared for the property transfer investigation concluded that the 123 Post Avenue Site was the source of the detected VOC contamination.

In May 1998, TCE was detected in Westbury Water District Well No. 11 at a concentration of 1.0 ug/l. Since then, TCE consistently has been detected in Well No. 11 at levels below the New York State drinking water standard of 5 ug/l. Trace concentrations of 1,2-DCE have also been sporadically detected in Well No. 11. PCE has never been detected in Well No. 11. The PCE, TCE and DCE results for Well No. 11 from 1995 through 2001 are summarized in Table 1-1.

The NCDH collected a groundwater sample from the water supply well at the Big M Car Wash of Westbury on October 31, 2000. The sample was analyzed at the NCDH laboratory for VOCs. PCE, chloroform and methyl tert-butyl ether were detected at concentrations of 1.3 ug/l, 4 ug/l and 15 ug/l, respectively. TCE and 1,2-DCE were not detected in the car wash supply well.

Notes:

Concentrations are micrograms per liter
 ND: Not detected (less than 0.5 microgram per liter)

An irrigation well for the Cemetery of the Holy Rood located approximately 1,800 feet east of Post Avenue (outside of the study area) was sampled by the NCDH and NYSDEC on May 10, 2001. The approximate location of this well is shown on Figure 1-1. The screen zone for the irrigation well is 319 to 339 feet below ground surface. Eight VOCs were detected in the sample, including 1,1-dichloroethene (0.7 ug/l), 1,1-dichloroethane (3.0 ug/l), cis-1,2-DCE (1.5 ug/l), chloroform (0.8 ug/l), 1,1,1-trichloroethane (0.8 ug/l), carbon tetrachloride (0.6 ug/l), TCE (14 ug/l) and PCE (35 ug/l). Due to the long distance of the irrigation well from the site in the sidegradient direction, as well as the relatively deep screen zone of the well, it is highly unlikely that the VOCs detected in the cemetery irrigation well are the result of activities at the site, and therefore, likely represent a separate contaminant plume from other sources.

Periodic sampling of ambient indoor air has been performed by the NCDH and NYSDEC at locations surrounding the site since 2000. PCE concentrations above the New York State Department of Health exposure limit for residential properties of 100 micrograms per cubic meter (ug/m^3) were detected in samples collected from the basement of the shopping center immediately north of the site (up to $1,930 \text{ ug}/\text{m}^3$) and from the superintendent's apartment on the first floor of the apartment building immediately west of the site (up to $7,400 \text{ ug}/\text{m}^3$). Outdoor air samples collected adjacent to the superintendent's apartment contained PCE at concentrations ranging from $1.4 \text{ ug}/\text{m}^3$ to $15 \text{ ug}/\text{m}^3$. Since the impacted off-site properties are located outside of the area of highly contaminated groundwater in the upgradient and sidegradient directions, respectively, the detected PCE is likely attributable to migration through the unsaturated zone, rather than volatilization from groundwater. These elevated PCE concentrations have been addressed by the NCDH and NYSDEC through installation and operation of an active air filtration unit in the basement of the adjacent shopping center from June 2001 through November 2001, and two air filtration units in the superintendent's apartment from June 2001 through August 2001. PCE concentrations have been less than $100 \text{ ug}/\text{m}^3$ in all samples collected since June 2001 from the shopping center basement and the superintendent's apartment, including samples collected after operation of the air filtration units was discontinued. It is likely that operation of the on-site SVE system has reduced the migration of vapors to off-site buildings.

A passive venting system was incorporated into the design of the newly constructed assisted living facility at 117 Post Avenue, located immediately south of the LIRR tracks from the site. The system was constructed to prevent exposure of residents to vapors that may volatilize from groundwater and migrate into the building.

Section 2

2.0 STUDY AREA INVESTIGATION

Provided below is a summary of the field activities conducted as part of the OU2 Remedial Investigation. The field activities were performed in accordance with the approved RI/FS Work Plan, dated March 2001, except for the collection of Hydropunch groundwater samples. Based on the direct push groundwater sample results, which delineated the vertical extent of contamination in the northern portion of the study area, and due to concerns about drilling through a clay layer in the southern portion of the study area, Hydropunch samples were not collected.

2.1 Overview of Field Activities

The field activities performed within the study area were conducted in a phased approach with the ultimate goal of locating the source(s) of groundwater contamination and defining the horizontal and vertical limits of a VOC plume that has been documented in the vicinity of the 123 Post Avenue Site. To accomplish this goal, a number of investigation techniques were utilized. Field activities and supporting investigation activities included the following:

- Existing well survey;
- Soil conductivity logging;
- Direct push groundwater sampling;
- Permanent monitoring well construction;
- Gamma logging;
- Monitoring well sampling; and
- Well surveying.

Delineation of the plume was conducted through direct push groundwater sampling along transects constructed perpendicular to the regional groundwater flow direction, and the construction and sampling of five permanent monitoring wells.

A detailed description of the field program is presented below.

2.2 Site Preparation

Prior to conducting the investigation and sampling activities, a staging area for materials and equipment was established at the Village of Westbury Department of Public Works (DPW) yard on Dover Street. The staging area was also the location of the temporary decontamination pad and the roll-off containers for drill cuttings. Potable water for drilling and decontamination of equipment was obtained at the DPW yard, with permission of the Department of Public Works.

2.3 Existing Well Survey

A review of NYSDEC Region 1 files was conducted to identify water supply wells within the vicinity of the study area. The only supply wells identified in the study area were Westbury Water District Supply Well No. 11 (total depth of 538 feet below ground surface) and the supply well at the Big M Car Wash of Westbury (total depth of 65 feet below ground surface). These wells are located approximately 2,000 feet south-southwest of the site as shown in Figure 1-1. In addition, an irrigation well was identified at the Cemetery of the Holy Rood. This well is screened from 319 feet to 339 feet below ground surface, and is located approximately 1,800 feet east of Post Avenue (see Figure 1-1). According to cemetery officials, this well has only been used for irrigation and was never utilized for potable water supply.

The nearest downgradient public water supply well outside of the study area is Roosevelt Field Water District Well No. 5 (N-7957). This well is located approximately 1 mile south-southwest of the 123 Post Avenue Site and is screened from 433 to 518 feet below ground surface. In 1997, a carbon treatment system was installed at Well No. 5 for removal of VOCs, in particular, PCE and TCE. In 1999, Freon-113 was detected in Well No. 5. In response, the well was shut down and a packed tower aeration system was constructed. Well No. 5 was restarted in August 2001. Since then, water samples collected from the well prior to treatment have

contained PCE, 1,2-DCE, 1,1-dichloroethene, 1,1,1-trichloroethane and Freon-113 at concentrations of 10 ug/l or less, and TCE at concentrations up to 60 ug/l.

2.4 Soil Conductivity Logging

As part of the investigation, two locations were selected for continuous soil conductivity logging. The locations, designated CP-1 and CP-2, were chosen based on their distance from the site, and from Westbury Water District Well No. 11 where the lithology has been previously recorded.

The soil conductivity logging was performed by Zebra Environmental Corporation on March 26, 2001. The conductivity probe was driven to maximum achievable depths using a truck mounted direct push rig. The depths reached were 81 feet below ground surface at CP-1 and 92 feet below ground surface at CP-2. The conductivity log was generated as the probe was advanced. Upon completion of each log, the borehole was backfilled to ground surface with bentonite pellets. The soil conductivity logs are provided in Appendix A. Results of the soil conductivity logging are provided in the discussion of geology in Section 3.0.

2.5 Direct Push Groundwater Sampling

Groundwater samples were collected at 20 locations using the direct push sampling method. At each location, groundwater samples were collected beginning at the maximum achievable depth (up to 120 feet below ground surface) and progressing upward at 20-foot intervals to the water table (approximately 40 feet below ground surface). Each sample was collected using new dedicated polyethylene tubing and a decontaminated stainless steel check valve. Prior to sample collection at each interval, approximately 1 to 2 gallons of groundwater were purged from the polyethylene tubing (between approximately 3 and 20 tubing volumes, depending on the sample depth). Purge water was collected and disposed to the Nassau County sanitary sewer system with the approval of the Nassau County Department of Public Works. Field parameters (dissolved oxygen, pH, salinity, specific conductivity, temperature and

turbidity) were measured after purging and prior to sample collection. These measurements are included in Appendix B.

Filled sample bottles were immediately placed into an iced cooler for overnight delivery under chain of custody procedures to the laboratory. Each sample was analyzed for Target Compound List (TCL) VOCs by the NYSDEC laboratory utilizing 24-hour turnaround time. Analytical results are discussed in Section 4.0.

After sampling was completed, each probe hole was backfilled to ground surface with bentonite pellets. All nondedicated groundwater sampling equipment (direct push rods and check valve) were decontaminated at the decontamination pad using a steam cleaner.

2.6 Borehole Gamma Logging

In order to determine subsurface stratigraphy, in particular the presence of significant clay layers/confining units, gamma logging was performed at the boreholes for wells OU2-3 through OU2-5 by Aqua Terra Geophysics, Inc. At these locations, a gamma logging probe was lowered through the augers when the maximum drilling depth was reached. Gamma logs are included in Appendix C. Results of the gamma logging are provided in Section 3.0.

2.7 Monitoring Well Construction

Five monitoring wells (designated OU2-1 through OU2-5) were constructed in the study area downgradient of the 123 Post Avenue Site. The wells were constructed between May 14 and August 6, 2001, by Land, Air, Water Environmental Services, Inc. The locations of the monitoring wells were selected based on the results of the direct push groundwater samples and site access conditions. Except for well OU2-1, the wells were located adjacent to the probe hole locations at which the maximum VOC concentrations were detected. Construction of an assisted living facility at the 117 Post Avenue property prevented the construction of OU2-1 until August 2001, and newly-installed subsurface utilities necessitated that the well be placed west of the

most contaminated probe hole in this area (P-6). All well screens were installed at the depths of the greatest VOC contamination detected in the direct push samples.

The monitoring well boreholes were drilled using 4 1/4-inch ID hollow stem augers. Drill cuttings were monitored for the presence of VOCs using a PID and contained in 55-gallon drums. The drums were transported to the Village of Westbury DPW yard and the cuttings were placed into a roll-off container for subsequent disposal as nonhazardous waste.

Upon completion of drilling at each borehole, a monitoring well was installed. Each well was constructed with 2-inch diameter, Schedule 40, flush-joint PVC riser pipe and 0.010-inch slot well screen. The screen length was 10 feet for all wells except OU2-1, which was constructed across the water table with a screen 15 feet in length. Clean No. 1 grade sand was placed through the augers around the well screen to at least 2 feet above the top of the well screen. A 2 to 3-foot thick bentonite seal was placed above the sand pack. The remaining annular space was pressure grouted through the augers with a cement-bentonite grout. A flush-mounted well vault was cemented in place at ground surface to complete the well construction. Monitoring well construction details are summarized in Table 2-1. Between well locations, the drill rig, augers and tools were cleaned with high-pressure steam at the decontamination pad. Boring logs and monitoring well construction diagrams are included in Appendix D.

Drilling conditions at OU2-3 indicated the existence of a clay layer at approximately 117 feet below ground surface as the direct push sampler encountered very tight material at this depth. Gamma logging at this location did not provide verification of the clay layer because the probe could not be advanced deeper than 112 feet due to sand in the augers. Well OU2-3 was installed to a depth of 100 feet below ground surface based primarily on the direct push groundwater sample results in this area (P-12). Well OU2-4 was installed to a depth of 114 feet below ground surface. Drilling conditions and the gamma log at the location of OU2-4 indicated the presence of a significant clay layer at approximately 115 feet below ground surface. After the well was constructed and the auger flytes removed from the ground, a dark gray to black clay was observed on the lead auger. At OU2-5, the augers were advanced to 130 feet below ground

Notes:

bgs - below ground surface
msl - mean sea level

surface; however, due to running sands, the well could only be set to a depth of 121 feet below ground surface.

The monitoring wells were developed by pumping and surging to remove sediment from the well and to ensure a good hydraulic connection between the well and the surrounding formation. A 2-inch diameter submersible pump with new, dedicated polyethylene tubing was used for well development.

Water quality measurements of dissolved oxygen, pH, specific conductivity, temperature and turbidity were collected at regular intervals during development. Development water was collected in DOT-approved 55-gallon ring-top drums, transported to the Village of Westbury DPW yard and discharged to the Nassau County sanitary sewer system with approval of the Nassau County Department of Public Works.

2.8 Monitoring Well Sampling

Groundwater samples were collected from monitoring wells OU2-2, OU2-3, OU2-4 and OU2-5 on June 27, 2001. Well OU2-1 was sampled on August 10, 2001.

The monitoring wells were sampled by first measuring the depth to water and depth to bottom of the well. These measurements were used to calculate the volume of standing water in the well. Prior to sampling, three to five well volumes were purged from each well using a Grundfos RediFlo2 2-inch submersible pump and new, dedicated polyethylene tubing, or a new, disposable bailer. Purge water was monitored for dissolved oxygen pH, specific conductivity, turbidity and temperature. Purging ended when the field parameters stabilized (three consecutive readings within 10%) and at least three well volumes had been purged.

As approved by the NYSDEC Project Manager, groundwater samples from OU2-2 through OU2-5 were collected from the pump discharge after the flow rate had been reduced to approximately 100 milliliters per minute. The sample collected from OU2-1 was collected using a dedicated disposable polyethylene bailer. For each sample, laboratory-supplied sample bottles

were filled and immediately placed into an iced cooler. The samples were shipped under chain of custody procedures for overnight delivery to the NYSDEC laboratory for analysis. As directed by NYSDEC, purge water from OU2-2, OU2-3, OU2-4 and OU2-5 was discharged to the ground surface adjacent to each well. Purge water from OU2-1 was contained and transported to the Village of Westbury DPW yard and discharged to the Nassau County sanitary sewer system with approval of the Nassau County Department of Public Works.

All well samples were analyzed for TCL VOCs. In addition to TCL VOC analysis, the sample from OU2-3 was analyzed for total iron and total manganese for potential groundwater treatment system design purposes. All samples were analyzed by the NYSDEC laboratory. The analytical results are discussed in Section 4.0.

Appropriate QA/QC samples, including matrix spike and matrix spike duplicate samples, were collected to meet the Data Quality Requirements described in the RI/FS Work Plan for the 123 Post Avenue Site. A trip blank accompanied each shipment that included VOC samples.

2.9 Well Surveying

The monitoring well locations were surveyed on August 30, 2001, for horizontal and vertical control by YEC, Inc. Elevations of measuring points on the top of the PVC riser for each well were tied to the National Geodetic Vertical Datum of 1929 (NGVD-1929). Horizontal control was tied to the New York State Plane Coordinate System, North American Datum of 1983 (NAD 1983). Elevation data are included in Table 2-1. The survey report is included in Appendix E.

2.10 Health and Safety Program

Prior to performance of the field program and as part of the RI/FS Work Plan, a site-specific Health and Safety Plan (HASP) was prepared in order to establish health and safety requirements, responsibilities and procedures to protect workers during the field investigation. This plan was used to supplement the generic HASP included in the draft "Remedial

Investigation and Feasibility Study Generic Work Plan, Dry Cleaner Sites,” dated February 1996, which was prepared for the NYSDEC by D&B. All field activities conducted as part of the RI were performed in accordance with the HASP.

2.11 Quality Assurance/Quality Control Program

As part of the RI/FS Work Plan, a Quality Assurance and Quality Control (QA/QC) Plan was prepared. The QA/QC Plan describes the sample collection and analytical procedures to be used to ensure high quality, valid data. QA/QC samples collected during this RI included trip blanks and matrix spike/matrix spike duplicate samples. These samples were collected to ensure quality control for the groundwater samples obtained during the investigation.

All analyses were performed using 1995 NYSDEC Analytical Services Protocol (ASP) methods. Since the analytical data packages provided by the NYSDEC laboratory are ASP Category A rather than Category B, data validation was not performed on the analytical results.

Section 3

3.0 HYDROGEOLOGY

3.1 Regional Geology and Hydrogeology

Long Island is composed of a thick sequence of unconsolidated sediments overlying a southeasterly sloping bedrock surface. In central Nassau County near the study area, the thickness of the unconsolidated sediments is approximately 1,000 feet (D.A. Smolensky, H.T. Buxton and P.K. Shernoff, 1989, Hydrologic Framework of Long Island, New York, United States Geological Survey Atlas HA-709).

The sediments consist of a series of marine deposits overlying bedrock capped by glacial deposits. Collectively, the sediments consist of interbedded layers of sand, gravel, silt and clay. From deepest to shallowest, the marine sediments comprise the Raritan Formation (Lloyd aquifer and Raritan confining unit) and the Magothy aquifer. The overlying glacial sediments are collectively known as the Upper Glacial aquifer. The Lloyd, Magothy and Upper Glacial sediments form the major aquifers of Long Island, while the Raritan confining unit separates the Lloyd and Magothy aquifers and limits flow into and out of the Lloyd aquifer.

In the vicinity of the study area, the Lloyd aquifer is approximately 250 feet thick and consists of gravel, sand, sandy clay and clay. The Raritan confining unit is approximately 100 feet thick and is comprised of clay and silty clay. The Magothy aquifer is approximately 550 feet thick and consists of gravel, sand and sandy to solid clay. Gravel layers are common at the base of the Magothy aquifer. The Upper Glacial sediments are approximately 100 feet thick and are comprised of glacial outwash deposits, including fine to coarse sands and gravels with local layers of clay.

3.2 Study Area Geology and Hydrogeology

The geology and hydrogeology of the study area has been determined from information derived during the field investigation and from literature sources. The field activities that provided information included groundwater direct push probe holes, direct push soil conductivity

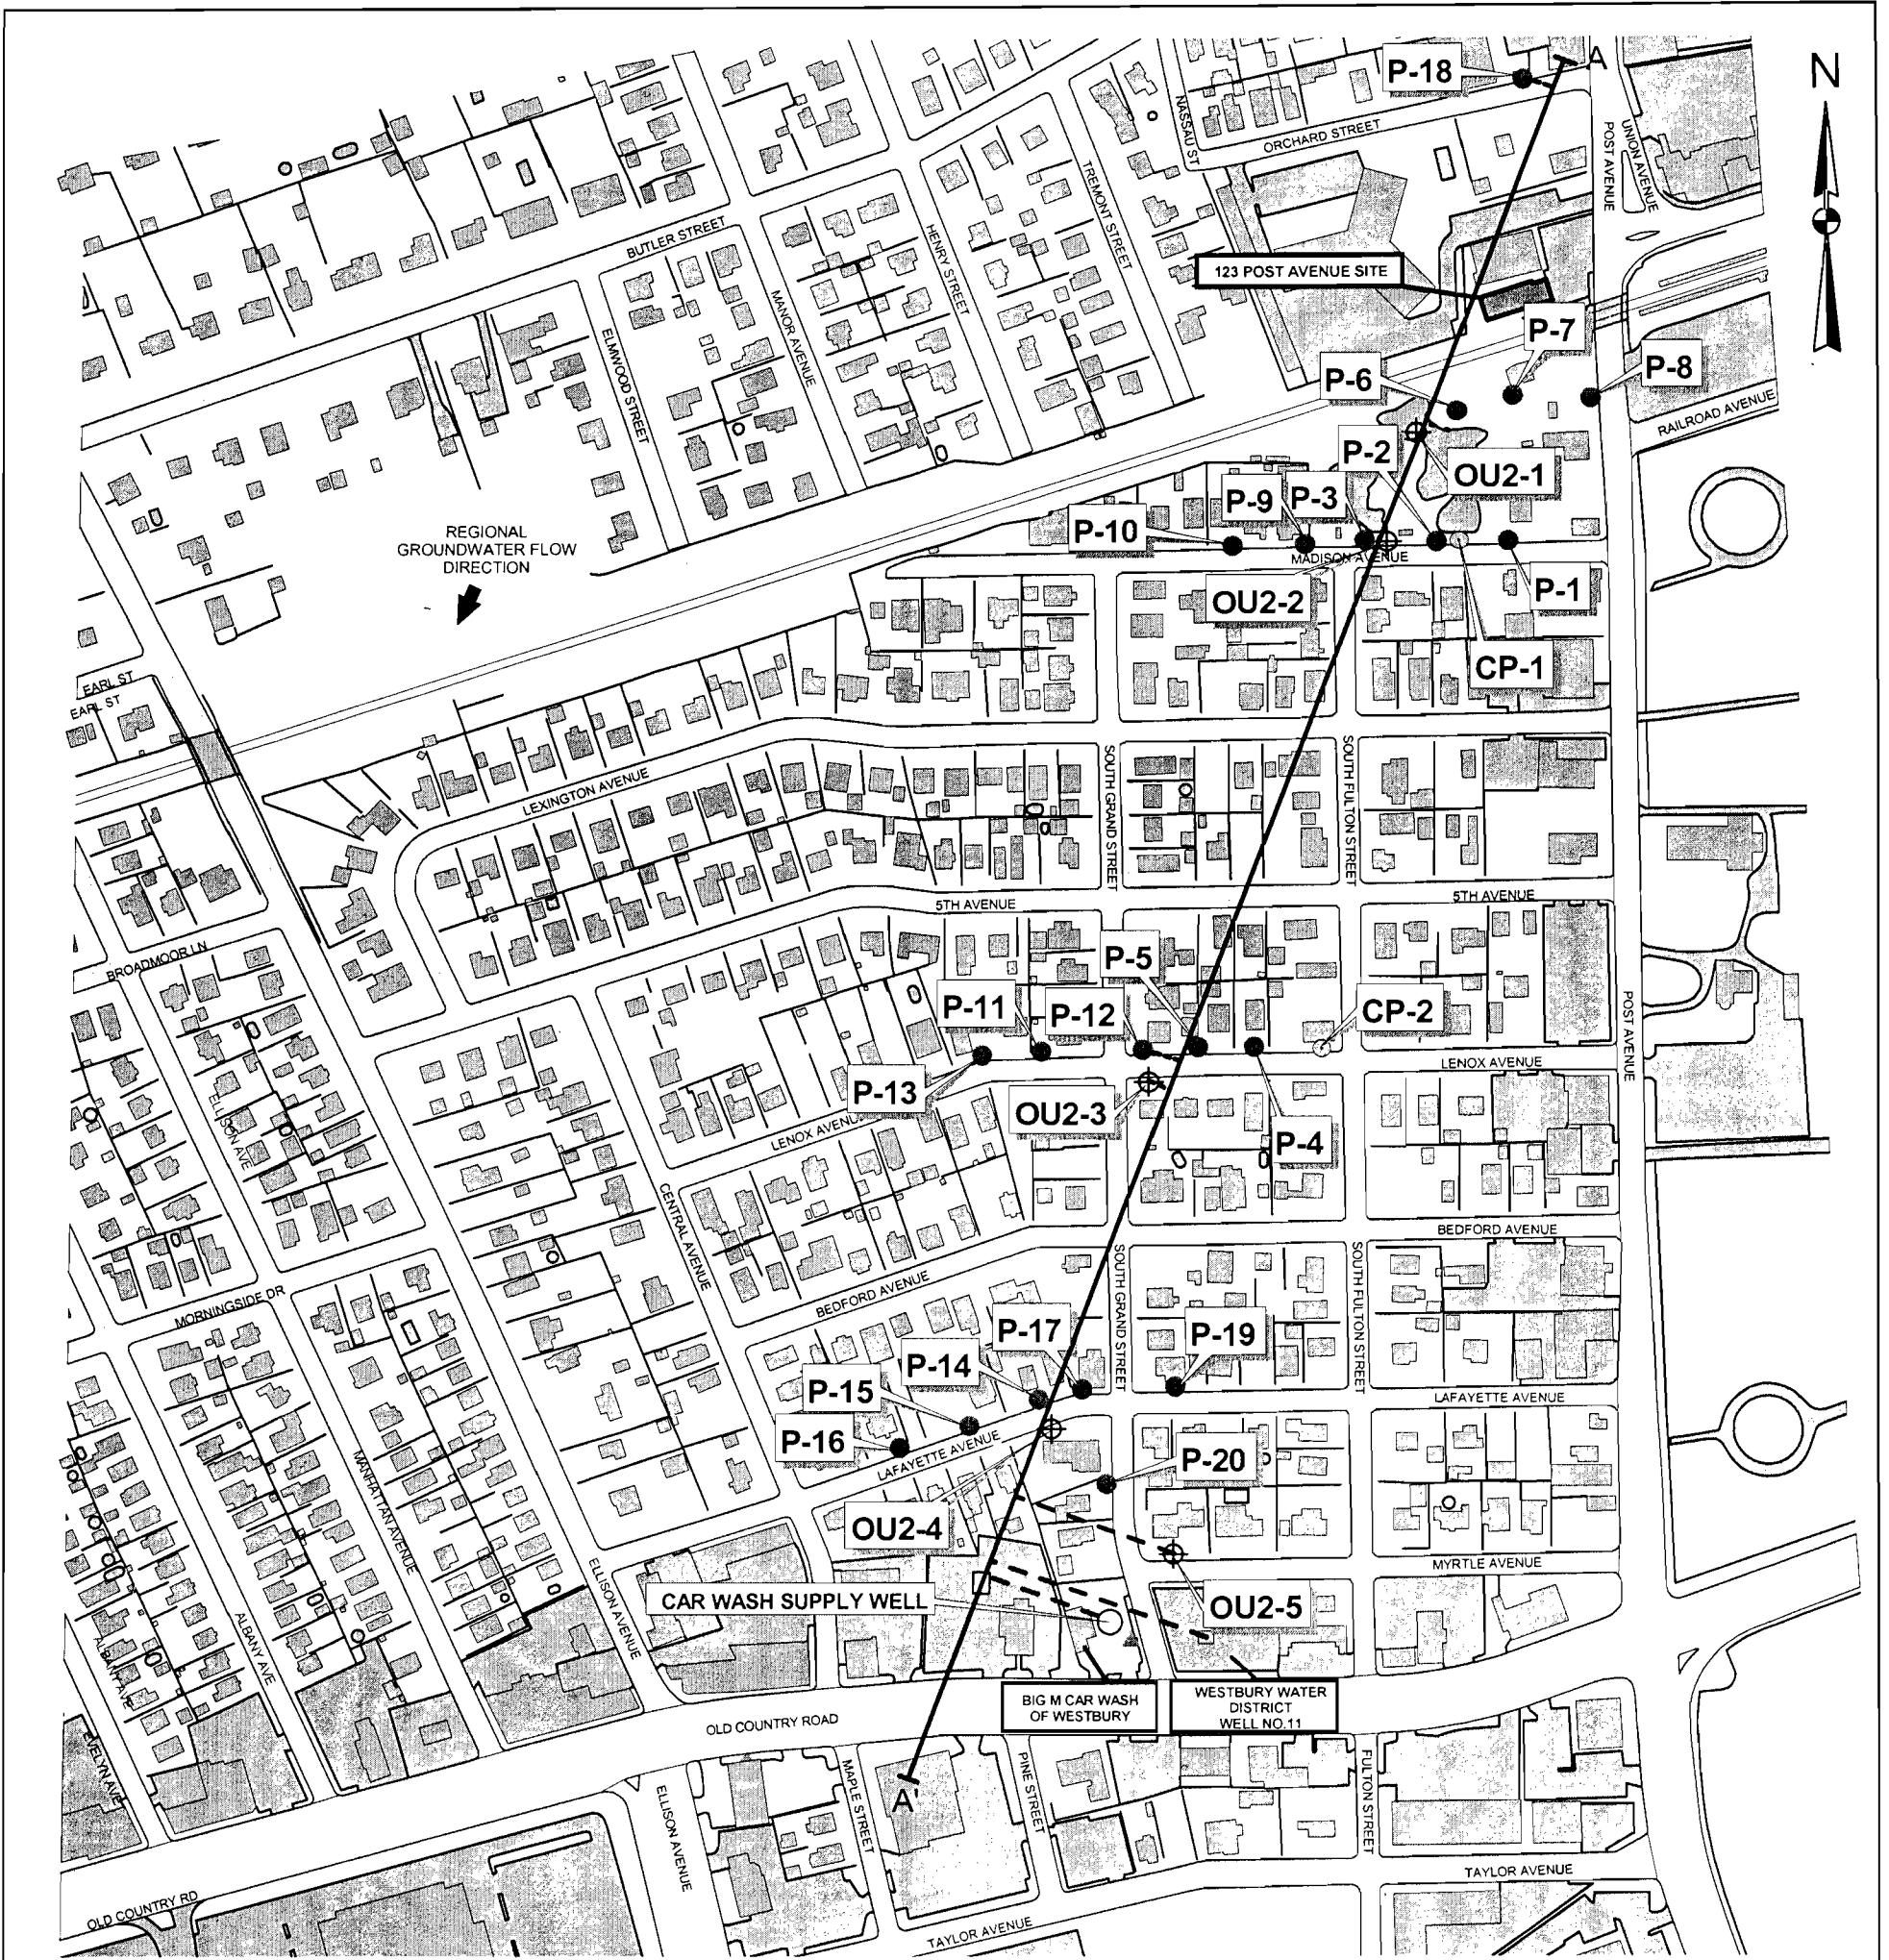

logs, gamma logs and borehole logs. Research information was derived from the well logs of the nearby water supply wells, including the Big M Car Wash of Westbury supply well and Westbury Water District Well No. 11. The logs of these wells are provided in Appendix F. The locations of all subsurface data points utilized during the OU2 Remedial Investigation are shown on Figure 3-1.

3.2.1 Study Area Geology

The Upper Glacial sediments within the study area generally consist of fine to coarse sand with varying amounts of silt and gravel. The primary unit observed during field activities was fine-to-medium grained sand. The soil conductivity logs from CP-1 and CP-2 (see Appendix A) show that the upper 80 feet of glacial sediments at these locations consist of sand with little variation. The gamma logs for well bore holes OU2-2 through OU2-5 (see Appendix C) and boring logs from the five permanent monitoring wells (see Appendix D) also show that the stratigraphy is mostly sand to approximately 115 feet below ground surface.

A clay layer was identified below the glacial sediments in the central and southern portions of the study area. The clay layer was encountered at approximately 115 feet below ground surface in the borings for permanent wells OU2-3 and OU2-4, located approximately 1,200 and 1,700 feet south-southwest of the site, respectively. Clay was not identified in the boring for well OU2-5 to a depth of 130 feet below ground surface. The driller's log for the Big M Car Wash supply well shows fine-to-medium sand to 65 feet below ground surface and a gray clay from 66 to 120 feet below ground surface, which was the bottom of the borehole. The log for Westbury Water District Well No. 11 shows a unit consisting of sand, brown clay and iron oxide from 82 to 136 feet below ground surface, and four clay layers, ranging from 4 to 31 feet thick, between depths of 136 and 260 feet below ground surface. These logs indicate that the clay layers are not continuous in the southern portion of the study area. As such, the clay would possibly limit, but not prevent, vertical migration of contaminants. The logs for the Big M Car Wash supply well and Well No. 11 are provided in Appendix F. A cross-section summarizing the study area geology is shown on Figure 3-2.

FIGURE 3-2

3.2.2 Study Area Hydrogeology

The water table was encountered in the study area at depths ranging from 39.4 to 45.6 feet below ground surface (see Table 3-1). The groundwater elevations measured in the five monitoring wells constructed during this remedial investigation (OU2-1 through OU2-5) were highest in the northernmost well OU2-1 (62.30 feet) and lowest in the southernmost well OU2-5 (59.7 feet), indicating a southerly direction of groundwater flow. Since the permanent well locations were selected based on the direct push groundwater sample results, the wells were installed in a nearly linear configuration. As a result, a groundwater elevation contour map could not be prepared. However, based on the VOC results from the direct push groundwater sample locations (discussed in Section 4.0), which define a narrow contaminant plume, the groundwater flow direction within the study area is toward the south-southwest.

Section 4

4.0 NATURE AND EXTENT OF CONTAMINATION

This section presents the analytical results for the groundwater samples collected during the Operable Unit 2 Remedial Investigation for the 123 Post Avenue Site, and discusses the nature, extent and significance of contamination detected upgradient and downgradient of the site. The extent of contamination is based on a comparison of contaminant concentrations to standards, criteria and guidelines (SCGs) selected for the site, which are described below.

4.1 Identification of Standards, Criteria and Guidelines

This section provides the standards, criteria and guidelines that are used to identify the contaminants of concern, and on a preliminary basis, assess the potential threat to human health and the environment. The medium for which the SCGs have been identified is groundwater.

For review and interpretation of the groundwater sample results, the SCGs selected for the site are based on NYSDEC Technical and Operational Guidance Series (TOGS) (1.1.1), *Ambient Water Quality Standards And Guidance Values and Groundwater Effluent Limitations* (1998). These water quality standards and guidance values were developed to provide maximum ambient contaminant concentrations to protect New York State groundwater and surface water, based on best usage. Analytical results from groundwater samples collected during this investigation are compared to Class GA standards and guidance values, for which the best usage is potable water supply. The Class GA groundwater standards and guidance values are included in the analytical results summary tables.

4.2 Analytical Results

4.2.1 Volatile Organic Compounds

Based on previous investigations at the 123 Post Avenue Site and the groundwater sample results from this investigation, three chlorinated compounds typically associated with dry cleaner sites, tetrachloroethene (PCE), trichloroethene (TCE) and 1,2-dichloroethene (1,2-DCE),

have been identified as contaminants of concern. As described in Section 1.1, PCE is used as a dry cleaning solvent, and TCE and 1,2-DCE are breakdown products of PCE.

The analytical results for the groundwater direct push and the monitoring well samples are summarized in Tables 4-1 and 4-2, respectively. Laboratory data sheets are provided in Appendix G. As shown in Table 4-1, for most direct push samples, the only VOCs detected were PCE, TCE and/or 1,2-DCE. The only other VOCs detected in any of the direct push samples were 1,1,2-trichloroethane (1,1,2-TCA) detected in three samples, chloroform detected in one sample and methyl tert-butyl ether (MTBE) detected in six samples. The detections of 1,1,2-TCA were in the three samples containing the highest total VOC concentrations, P-3 (44-48' and 56-60') and P-6 (40-44'), suggesting that the 1,1,2-TCA may also be associated with the 123 Post Avenue Site. MTBE was detected in upgradient probe hole P-18 and in probe holes in the southern portion of the study area (P-17, P-19 and P-20), and is attributable to a gasoline release upgradient of the site.

As shown in Table 4-2, 13 compounds other than PCE, TCE or 1,2-DCE were detected in samples collected from the monitoring wells. However, only two of these compounds were detected at concentrations exceeding NYSDEC Class GA groundwater standards or guidance values. These exceptions are methacrylonitrile, which was detected in well OU2-2 at 9 ug/l (compared to the standard of 5 ug/l), and acetone, which was detected in well OU2-2 at 670 ug/l and in well OU2-4 at 130 ug/l. Since acetone is a common laboratory artifact and was not detected in any of the direct push groundwater samples, the acetone detections are not considered to be related to the site.

The concentrations of total targeted VOCs (PCE, TCE and 1,2-DCE) in direct push and monitoring well samples range from non-detect to 11,294.8 ug/l. The greatest concentrations of targeted VOCs were detected nearest the 123 Post Avenue Site, at the 117 Post Avenue property (P-6) and immediately south on Madison Avenue (P-3 and OU2-2). Concentrations of total targeted VOCs decrease to the south-southwest, downgradient of the site. In addition, the depth of the zone most highly impacted by the targeted VOCs increases to the south-southwest.

The approximate horizontal extent of total targeted VOCs detected in probe holes and monitoring wells in the study area is shown on Figure 4-1. For each probe hole, the maximum concentration of total targeted VOCs is shown. The chlorinated VOC plume is depicted by total targeted VOC contours of 100 ug/l, 1,000 ug/l and 10,000 ug/l, and extends from the 123 Post Avenue Site in a south-southwest direction. The plume is fairly narrow (as delineated by 100 ug/l contour), with approximate dimensions of 200 feet wide by at least 1,800 feet long (extending to south of Lafayette Avenue). At probe hole P-18, upgradient of the site, the total maximum targeted VOC concentration was 11 ug/l.

The vertical distribution of PCE, TCE and 1,2-DCE in groundwater within the study area is depicted in cross-sectional view on Figure 4-2. The cross-section is oriented along the center axis of the identified plume parallel to groundwater flow. The cross section shown on Figure 4-2 indicates that the plume emanates from the vicinity of the 123 Post Avenue Site and gradually sinks within the aquifer toward the south-southwest. Based on the detected VOC concentrations, the plume appears to be sinking at a rate of approximately 1 vertical foot per 10 horizontal feet. The maximum thickness of the plume (total targeted VOCs greater than 100 ug/l) is approximately 60 feet. The thickness of the more concentrated plume (total VOCs greater than 1,000 ug/l) is approximately 35 to 40 feet.

A feature apparently reducing the vertical migration and extent of the plume is the clay layer observed at approximately 115 feet below ground surface in the southern portion of the study area at monitoring wells OU2-3 and OU2-4 (Figure 4-2). Although significant clay was not noted at well OU2-5 to a depth of 130 feet below ground surface, the driller's log for Westbury Water District Well No. 11 shows sand, brown clay and iron oxide from 82 to 136 feet below ground surface, and four clay layers from 4 to 31 feet thick between 136 and 260 feet below ground surface. In addition, the driller's log of the Big M Car Wash supply well shows clay from approximately 65 feet to the bottom of the well borehole at 120 feet below ground surface.

DISTRIBUTION OF PCE, TCE AND 1,2 DCE IN GROUNDWATER

FIGURE 4-2

As shown in Tables 4-1 and 4-2, and on Figure 4-2, the plume is primarily comprised of PCE. The relative percentages of PCE, TCE and 1,2-DCE change with distance from the site throughout the plume, indicating chemical degradation. Near the source area at probe hole P-3, the maximum total targeted VOC concentration is 8,225 ug/l, with PCE, TCE and 1,2-DCE comprising 99.7%, 0.7% and 0.3% of the total, respectively. In the central portion of plume at probe hole P-12, approximately 1,000 feet downgradient of the 123 Post Avenue Site and about 60 feet below the water table, the maximum total targeted VOC concentration of 2,026 ug/l was comprised of 83.9% PCE, 3.2% TCE and 12.8% 1,2-DCE. Near the leading edge of the plume at well OU2-4, the maximum total targeted VOC concentration was 140 ug/l, with 92.8% PCE, 2.8% TCE and 4.3% 1,2-DCE.

4.2.2 Inorganics

For future evaluation of potential groundwater treatment processes, one groundwater sample was also collected for analysis of iron and manganese. This sample was collected from well OU2-3 located near the center of the plume. OU2-3 is screened from 90 to 100 feet below ground surface. The iron and manganese concentrations from the unfiltered sample were 450 and 760 mg/l, respectively. Although these concentrations are above the combined NYSDEC Class GA groundwater standards of 300 mg/l, the results are typical for groundwater within the Upper Glacial aquifer.

Section 5

5.0 HUMAN HEALTH EXPOSURE ASSESSMENT

5.1 Introduction

The purpose of this section is to evaluate the potential human health exposures to the chemical contamination detected in groundwater downgradient of the 123 Post Avenue Site. Potential exposures are evaluated on the basis of the environmental setting of the study area and information on the nature and extent of contamination as described in previous sections of this report. Relevant environmental information is discussed in the context of current and potential human contact with contaminants of concern at potential locations where human exposure could occur without any remedial measures implemented to mitigate exposure to contaminants.

As with any risk assessment, this assessment is not intended to predict disease outcome, but rather is meant to be used as a tool to make decisions regarding the need for remediation. Given the available information for the study area, and keeping the purpose of this assessment in mind, the following evaluation for the 123 Post Avenue off-site area is qualitative with an emphasis on exposure assessment.

5.2 Background Information

Information regarding the site location, setting and historic information is present in Sections 1.0 and 3.0 of this report. A detailed description of the activities conducted during this investigation is presented in Section 2.0, and the nature and extent of contamination detected in off-site groundwater is described in Section 4.0.

Land use within the study area is primarily residential, with commercial businesses along the west side of Post Avenue and along Old Country Road. The study area is served by public water and sewer systems.

The depth to groundwater within the study area ranges from approximately 39 to 46 feet below ground surface and the groundwater flow direction is toward the south-southwest. Two

water supply wells were identified within the study area. One of these is Westbury Water District Well No. 11, which supplies potable water, and the other well is at the Big M Car Wash of Westbury, which supplies water for car washing (see Figure 1-1). Both of these wells are located downgradient of the 123 Post Avenue Site on Old Country Road.

5.3 Human Health Exposure Assessment

The purpose of this exposure assessment is to determine how and when an individual might be exposed to the contaminants of concern migrating from the 123 Post Avenue Site. A contaminant of concern is any chemical detected in a medium that could produce adverse health effects under the right conditions of dose and exposure. For exposure to occur, there must be a complete “pathway of exposure” where a person can come into contact with the contaminants. For a pathway to be complete, there must be: 1) a source or medium containing the contaminant(s) of concern; 2) a location where human contact could take place (that is, an exposure point); and 3) a feasible means for the contaminant(s) of concern to enter the person’s body. The person who could come in contact with the contaminant(s) of concern at an exposure point is called a “receptor.” The ways in which the contaminant(s) of concern can enter the body are called “routes of exposure.” Ingestion (oral exposure), dermal (skin contact) and inhalation (exposure by breathing) are considered in this (and other) human health exposure assessments. Consistent with the New York State Department of Health (NYSDOH) and other regulatory agencies, this assessment considers both current and potential future exposures. Since the scope of the Operable Unit 2 Remedial Investigation included only off-site groundwater, potential exposures to on-site groundwater, and contaminated soil or sediments at the site, will not be addressed by this exposure assessment.

As described in Section 4.0, based on site usage and the distribution of contaminants in groundwater downgradient of the site, the contaminants of concern have been identified as tetrachloroethene (PCE) and its breakdown products, trichloroethene (TCE) and 1,2-dichloroethene (1,2-DCE).

5.3.1 Groundwater

Groundwater downgradient of the site has been significantly impacted by VOCs, in particular PCE, TCE and 1,2-DCE. The identified plume (defined by the 100 ug/l contour) is relatively narrow (approximately 200 feet wide) and extends approximately 1,800 feet from the site. The total concentrations of PCE, TCE and 1,2-DCE detected in off-site groundwater range up to 11,295 ug/l.

There currently is no known human exposure to groundwater containing VOCs at concentrations above NYSDEC Class GA standards in the study area. Groundwater does not discharge to the ground surface and the closest public water supply (Westbury Water District Well No. 11) does not exceed drinking water standards. Potential future exposure via ingestion (drinking), dermal contact (washing) or inhalation (volatilization) is possible, should the impacted groundwater ever be utilized for potable supply. However, it is considered highly unlikely that additional potable supply wells would be constructed in the area of the plume due to the identified groundwater contamination and the absence of open space in the area.

The presence of clay layers in the southern portion of the study area may be limiting the vertical migration of contaminants. However, because the continuity of the clay layers is unknown, there may be a pathway for the VOCs to migrate into Westbury Water District Well No. 11 and possibly other water supply wells located farther downgradient of the site, such as Roosevelt Field Water District Well No. 5, which is located approximately 1 mile from the site. PCE, TCE and 1,2-DCE (among other contaminants) from currently unidentified sources have been detected in Roosevelt Field Well No. 5 above drinking water standards; however, treatment is provided for this water prior to distribution. Based on the current plume configuration and distance from the 123 Post Avenue Site to Roosevelt Water District Well No. 5, it is considered highly unlikely that the VOCs currently detected in Roosevelt Field Water District Well No. 5 are migrating from the 123 Post Avenue Site. However, there is currently no information to suggest that the 123 Post Avenue Site is or is not a source of the VOCs detected in Roosevelt Field Water District Well No. 5.

The detection of PCE in the sample collected in October 2000 from the car wash supply well indicates a complete pathway exists for dermal and inhalation exposure to impacted groundwater by car wash employees during car washing. However, since the detected concentration was only 1.3 ug/l, which is below the health-based NYSDEC Class GA groundwater standard of 5 ug/l, it is unlikely that this condition represents a significant exposure.

As described above, Roosevelt Field Water District Well No. 5 is located approximately 1 mile south-southwest (downgradient) of the 123 Post Avenue Site. Since the clay layers detected during the remedial investigation and shown on logs for wells in the area do not appear to be continuous, it is possible that the detected VOC contamination from the site could migrate to Roosevelt Field Water District Well No. 5. Based on the identified plume configuration, this represents a potential future exposure pathway if treatment of the water supply currently being provided is not continued.

5.3.2 Air

Exposure to the contaminants of concern released to air from groundwater through volatilization is a consideration. Air samples collected by others from the passive venting system constructed beneath the assisted living facility at 117 Post Avenue located across the LIRR tracks from the 123 Post Avenue Site, as well as outdoor air at the property, contained low levels of PCE, TCE and 1,1-dichloroethene (1,1-DCE). Although the PCE levels detected are at least an order of magnitude below the NYSDOH guideline for residential properties, the detections indicate that minor volatilization from groundwater may be occurring in the northern portion of the study area, where the plume is at the shallowest depths and where the highest VOC concentrations were detected (these detections may also be the result of subsurface migration of VOCs from the site through the unsaturated zone). Therefore, potential exposure to the contaminants of concern due to volatilization from groundwater into buildings within the study area is possible. Based on the concentrations detected in the air samples collected at the 117 Post Avenue property, it is unlikely that volatilization from groundwater represents a significant potential exposure to residents of the assisted living facility.

Since basements were observed in most of the residences within the study area (reducing the vertical distance between the impacted groundwater and the buildings), volatilization into other nearby buildings overlying the plume downgradient of the 117 Post Avenue property is possible. However, it is the experience of the NYSDOH, at sites with similar VOC concentrations in groundwater and comparable distances between impacted groundwater and overlying structures, that volatilization from groundwater does not represent a significant potential exposure pathway.

As discussed above, there is also a potential for inhalation exposure to VOCs from contaminated groundwater that may be utilized for car washing at the Big M Car Wash of Westbury. The contaminants of concern may be volatilized as the extracted groundwater is sprayed during car washing. Since PCE was detected in the car wash supply well, this pathway is complete. However, since the sample from the car wash supply well contained PCE at a concentration of only 1.3 ug/l, it is unlikely that this pathway represents a significant potential exposure.

5.3.3 Conclusions

Three current potentially complete pathways have been identified for human exposure associated with the groundwater contamination detected downgradient of the 123 Post Avenue Site. The first of these pathways is volatilization from groundwater into buildings within the study area. This potential exposure is greatest in the northern portion of the study area where the VOC concentrations are greatest and the groundwater is closest to the ground surface. Based on recent air sample results at the 117 Post Avenue property (located across the LIRR tracks from the site), which are well below NYSDOH guidelines, the potential exposure associated with this pathway is not considered significant at this property. Based on the experience of the NYSDOH at similar sites, the potential exposure for occupants of nearby buildings due to volatilization from groundwater is also currently not considered significant.

The remaining two potentially complete exposure pathways associated with groundwater contamination are for employees of the Big M Car Wash of Westbury and include dermal exposure to impacted groundwater utilized for car washing and inhalation exposure due to volatilization of contaminants from groundwater during car washing. While these exposure pathways are currently complete, the low VOC concentrations detected in the car wash supply well water indicate that these exposures currently are not significant.

An additional potential pathway for exposure to impacted groundwater could be completed if a water supply well is constructed within the plume area in the future. However, as described above, it is considered unlikely that any new wells will be constructed in this area.

Section 6

6.0 CONCLUSIONS AND RECOMMENDATIONS

The objectives of the Operable Unit 2 Remedial Investigation for the 123 Post Avenue Site were to:

- determine the nature and extent of groundwater contamination off-site and downgradient of the site;
- determine whether existing or potential impacts to human health and the environment exist; and
- determine if remediation of off-site groundwater contamination is warranted.

A primary focus of the investigation was to evaluate whether the site is a contributing source for the trace levels of TCE and 1,2-DCE that have been detected in Westbury Water District Well No. 11, located approximately 2,000 feet downgradient of the site.

6.1 Conclusions

- The configuration of the contaminant plume indicates that the source of the detected PCE, TCE and 1,2-DCE is the 123 Post Avenue Site;
- Since soil removal was conducted at the contaminated floor drains in August 1998, and no additional discharges presumably have occurred since then, the PCE concentration detected in on-site well MW-3 (16,000 ug/l) in October 2000 suggests that there may be continuing contaminant sources at the site, such as the former sanitary system, possible roof drain dry wells, storm water dry wells or dense nonaqueous phase liquid (DNAPL) at or below the water table.
- The identified contamination has apparently slightly impacted the water supply well at the Big M Car Wash of Westbury, located approximately 2,000 feet south-southwest of the 123 Post Avenue Site, due to the detection of PCE (1.3 ug/l) in this well in October 2000;
- Although complete human exposure pathways were identified for volatilization from groundwater (in the northern portion of the study area), and for direct contact and inhalation exposures for workers at the Big M Car Wash of Westbury, the low VOC concentrations detected in air samples at the 117 Post Avenue property and in the groundwater sample from the car wash supply well indicate that the VOCs detected in

groundwater currently do not represent a significant threat to human health at these locations; and

- Since the continuity of the clay layers identified in the southern portion of the study area is unknown, the 123 Post Avenue Site may be a contributing source for the TCE and 1,2-DCE detected in Westbury Water District Well No. 11 and Roosevelt Field Water District Well No. 5. However, it appears that other sources may be contributing to the detected contamination, for the following reasons:
 - the screen zones of Westbury Water District Well No. 11 and Roosevelt Field Water District Well No. 5 are deep (474 to 575 feet and 433 to 518 feet below ground surface, respectively);
 - the identified clay layers likely are limiting the vertical migration of contaminants;
 - PCE comprises the vast majority (up to 99.7%) of the plume emanating from the 123 Post Avenue Site, yet PCE has never been detected in Westbury Water District Well No. 11, even though PCE and TCE have similar solubilities in water (150 to 2,000 milligrams per liter and 1,100 to 1,400 milligrams per liter, respectively) and similar soil sorption coefficients (2.25 to 3.04 and 1.96 to 2.03, respectively); and
 - the detections of TCE, 1,2-DCE and other VOCs (total VOCs of 56.4 ug/l) in the irrigation well at the Cemetery of the Holy Rood (screened from 319 to 339 feet below ground surface and located approximately 1,800 feet east/sidegradient of the study area) indicates the presence of a deep VOC plume in the area.

6.2 Recommendations

- Even though currently there is little potential for adverse impacts to human health and the environment, due to the high levels of VOCs detected in groundwater off-site and downgradient of the 123 Post Avenue Site, consideration of groundwater remediation is warranted to mitigate continued contaminant migration and protect the Sole Source Aquifer for drinking water supply in and downgradient of the study area. Therefore, it is recommended that a Feasibility Study be conducted to evaluate options for remediation of the identified groundwater contamination.
- The permanent monitoring wells constructed as part of this investigation should be sampled on a semiannual basis to evaluate downgradient migration of the identified plume.
- The car wash supply well should be sampled on a semiannual basis to evaluate whether VOC concentrations in this well are increasing.

- An investigation should be conducted to determine the source(s) of the VOC contamination detected in the irrigation well at the Cemetery of the Holy Rood.
- An investigation should be conducted at the 123 Post Avenue Site to determine if there are continuing sources of contamination at the site.

Re: 123 Post Avenue Survey

Dear Mr. Wenz:

Enclosed please find survey notes for the 123 Post Avenue Survey. This is a copy of what was faxed to you earlier.

If you need anything further, please feel free to contact me.

Very truly yours

Y.S. Ed Chen, Ph.D., P.E.
President, YEC, Inc.

VOA RESULTS

SITE 123 POST

SDG: 225-01

PROJECT MANAGER: T. GIBBONS

Date: 08/27/01

These samples have been completed with all quality control parameters satisfactory.

Dilutions were prepared when required.

The results were given as via phone on 8/23/01. This did not include dilution results.
