1.0 INTRODUCTION

Rohm and Haas Company tasked URS Corporation (URS) with preparing this remedial investigation (RI) report, which presents, summarizes, and provides interpretations and conclusions regarding data gathered during RI field activities at the Former EMCA Site (Site No. 360025) located in Mamaroneck, Westchester County, New York. The RI was performed as per Consent Order between Rohm and Haas Company and the New York State Department of Environmental Conservation (NYSDEC). Unless otherwise noted, RI activities were performed in accordance with the *Field Investigation Plan* (including the Field Sampling Plan and Health and Safety Plan), and the *Quality Assurance Project Plan*. Both of these plans were submitted to the NYSDEC in September 1999 and were approved by NYSDEC prior to initiating September 1999 field investigations. The Field Investigation Plan was amended in May 2000 prior to conducting a secondary field investigation in July 2000. All changes to the work plan were reviewed by Rohm and Haas Company and NYSDEC.

1.1 Purpose of the Remedial Investigation

The purpose of the RI was to collect the data necessary to characterize subsurface contamination at the Former EMCA Site. The primary goal of RI activities was to obtain data for defining the level of concern with regard to remnant 1,1,2-trichlorotrifluoroethane (Freon 113) (previously identified at the site) and other potential contaminants. The RI was designed: to refine the current understanding of groundwater flow direction; to evaluate the presence of other organic/metal contaminants and their source(s); and to support discussion of exposure and potential impact to human and environmental receptors and the need for remedial action at the site. In addition, data collected as part of this RI will be used to evaluate whether the site can be removed from NYSDEC's list of Inactive Hazardous Waste Disposal Sites.

1.2 Site Description and History

The EMCA property is a 0.6-acre site located in a mixed residential/industrial area in Mamaroneck, New York (Figures 1 and 2). EMCA, formerly owned by Rohm and Haas Company, manufactured high conductivity precious metal paste used in circuits by the electronics industry. Manufacturing at the EMCA site began in 1960, Rohm and Haas purchased the site in 1984, and manufacturing ceased in 1988. Rohm and Haas transferred site ownership to UA-

Columbia Cablevision who later merged with TCI Cablevision of Westchester and then with Cablevision of Westchester, the current site owner.

1.3 Previous Investigations

As part of the real property transfer, UA-Continental Cablevision retained Goldberg-Zoino and Associates of New York (GZANY) to perform a preliminary site investigation. In 1988, GZANY conducted a field investigation that included advancing several soil borings and installing nine monitoring wells. Based on their investigation, GZANY identified soil and water contamination at the site.

In 1989, EMCA/Rohm and Haas Company retained Woodward-Clyde Consultants (WCC) to review GZANY's data, conduct follow-up investigations, and evaluate risks associated with site contamination. Based on these efforts, WCC concluded there is no significant risk to human health or the environment, and that remediation of groundwater and site soils is not warranted.

In 1992, TCI Cable of Westchester, Inc. (the owner at that time), subcontracted ENVIRON Corporation to collect indoor and outdoor air samples to evaluate potential health risk with regard to air quality. Based on this investigation, ENVIRON concluded there was no evidence to suggest that air quality at the facility would produce any adverse health effects to the occupants of the building.

Based on the site history and environmental site data existing at the time (1991), NYSDEC listed the former EMCA property as a NYSDEC Class 2 Inactive Hazardous Waste Site based on the presence of Freon 113. In March 1999, Rohm and Haas Company signed a Consent Order with the NYSDEC, agreeing to conduct additional investigations to further evaluate the nature and extent of site contamination.

On April 27, 1999, Rohm and Haas Company met onsite with representatives from the NYSDEC, New York State Department of Health (NYSDOH), Cablevision of Westchester, and URS Corporation (URS) to discuss the planned remedial investigation and to assess the condition of the monitoring wells installed during previous investigations. Three of the nine former onsite

wells (GZ-3, GZ-6, and GZ-9) were located. However, well GZ-9 had been cut down below ground surface and paved over. Moreover, GZ-9 showed evidence of asphalt staining and it is likely that surface run-off drains into it. Only two of the nine former wells (GZ-3 and GZ-6) were deemed acceptable for re-sampling. The remaining six wells, installed during the prior studies, could not be found.

1.4 Summary of Site Contamination From Previous Investigations

During previous investigations, groundwater, air, and soil were sampled and analyzed. Based upon the results of previous investigations, the medium of primary concern at the site is groundwater. The discussions provided below are based on data presented in the reports entitled, *Assessment of Subsurface Conditions, 605-609 Center Avenue, 604 and 612 Fayette Avenue, Mamaroneck, New York* (GZANY, 1988), *Groundwater Sampling Results, Former EMCA Site, Mamaroneck, New York* (WCC, 1989a) and *Risk Assessment, Former EMCA Site, Mamaroneck, New York* (WCC, 1989b). A summary of previously detected analytes is provided in Appendix A. The chemicals of potential concern (CPCs) in these media have been identified by comparing the previous results to the following current NYSDEC standards and guidelines:

- New York Sate Department of Environmental Conservation (NYSDEC). 2000. "Ambient Water Quality Standards and Guidance Values and Groundwater Effluent Limitations." *Technical and Operational Guidance Series* (1.1.1) (TOGS 1.1.1). April. Albany, NY: Division of Water.

- New York State Department of Environmental Conservation (NYSDEC). 1994. "Determination of Soil Cleanup Objectives and Cleanup Levels." *Technical and Administrative Guidance Memorandum* HWR-94-4046. Albany, NY: Bureau of Hazardous Waste Remediation.

These standards and guidelines were not available at the time previous samples were collected, and are used herein for comparison purposes only.

Chemicals found during previous investigations, which when compared to today's standards may be considered CPCs, are summarized below:

- Groundwater - Volatile organic compounds (VOCs) are the primary CPCs in this medium. Two rounds of analyses previously were conducted (Appendix A), the first in May 1988 and the second in March 1989. When the May 1988 results are compared to the current New York State Class GA drinking water standards, the following VOCs are exceeded: benzene, chloroethane, 1,2-dichloroethene (total), ethylbenzene, trichloroethene, 1,1,1-trichloroethane, and Freon 113. In March 1989, three additional compounds were detected at levels above current Class GA standards: acetone, tetrachloroethene, and vinyl chloride. However, one compound, chloroethane, which was present at a level of potential concern in May 1988, decreased to a level below current Class GA standards in 1989. Also, the distribution of detected analytes suggested an offsite source for benzene, ethylbenzene, and the chlorinated volatile compounds. Freon 113 was the only compound believed to be attributable to previous EMCA site activities. Refer to Figures 3 and 4 for results and distribution of previous groundwater analyses. Two groundwater samples also were analyzed for the following metals in May 1988: barium, copper, lead, silver and zinc. The metals results are all below current Class GA standards. It is noted however, the 1988 samples were analyzed for dissolved metals rather than total metals. Current NYSDEC standards require total metals analysis (follow-up metals analyses were conducted for this RI – refer to Section 4.3).

- Ambient Air - During August 1992, ENVIRON collected eight indoor and two outdoor ambient air samples at the facility. The samples were analyzed for acetone, benzene, 2-butanone, chloroethane, chloroform, 1,1-dichloroethane, cis-1,2-dichloroethene, trans-1,2-dichloroethene, ethylbenzene, Freon 113, methylene chloride, 1,1,2,2-tetrachloroethane, tetrachloroethene, 1,1,1-trichloroethane, trichloroethene, and toluene. Traces of several of these compounds were detected, although their presence may be related to use of cleaning solvents for janitorial use or other sources inherent to the building infrastructure (e.g,. chloroform emitted from tap water). It also was found that Freon 113 was used onsite to maintain video tape equipment. ENVIRON concluded that the level of contamination identified at the site was not a health concern to site workers. The results of the ENVIRON study are provided in Appendix B.

- Surface Soil – Surface soil was not analyzed during previous investigations. Refer to Section 4.3 for surface soil analyses (metals only) conducted as part of this RI.

- Subsurface Soil – During the GZANY May 1988 investigation, 14 priority pollutant volatile organics were detected in the soil samples. Of these 14 compounds, methylene chloride and toluene were detected in the laboratory method blank and, therefore, their presence in the soil samples is questionable. A summary of detected volatile organics is provided in Appendix A. In addition to the priority pollutant volatiles, several unknown volatile organics were tentatively identified in the library search. No priority pollutant acid extractable (AE) or base neutral (BN) extractable compounds were detected. However, several AE and BN extractable compounds were tentatively identified in the library search.

Except for Freon 113, the majority of volatile compounds were detected in highest concentration along the southeastern site boundary in the upgradient groundwater flow direction. This distribution suggested an offsite upgradient source for these compounds. The highest Freon 113 detections were found within the parking area along the northeastern portion of the site. None of the soil concentrations exceeded the standards, criteria, and guidance values (SCGs) provided in TAGM 4046. Therefore further investigation of subsurface soil was not included in the work plans for this RI nor is subsurface soil considered a media of primary concern.

1.5 Report Organization

This report is categorized into seven sections: Section 2.0 presents the physical characteristics of the site; Section 3.0 discusses the field investigation activities performed during the RI; Section 4.0 discusses the nature and extent of contamination; Section 5.0 describes contaminant fate and transport; Section 6.0 presents preliminary alternatives for site remediation; and Section 7.0 summarizes findings and presents recommendations.

2.0 PHYSICAL CHARACTERISTICS OF THE SITE

2.1 Site Topography and Land Use

The former EMCA site is located in a mixed use residential/industrial area. As shown in Figure 7, there are several industrial, manufacturing, and warehousing facilities within an approximate 500-foot radius of the site including: a dry cleaner, automotive and welding facilities, an auto collision shop, a furniture restoration and stripping facility, a garbage hauling facility, and other general light industrial businesses. There are also six residential properties within the 500-foot radius. Surrounding the industrialized area, the dominant land use is medium and high density residential.

Site topography is generally flat, although grades gradually decrease to the northwest toward the Sheldrake River (there is approximately 10 feet of relief between the site and the Sheldrake River). The surface of the site is almost entirely paved or covered by existing structures, although minor grassy areas exist generally along median strips between sidewalks and roadways.

As per a 1963 Village of Mamaroneck Sanborn Map (Appendix F), the EMCA property was the former site of three residential structures and associated garages.

A review of local potable water supplies was previously conducted and documented in the report entitled, *Risk Assessment, Former EMCA Site* (WCC 1989b). This review indicated that the primary water supply for Southern Westchester County was obtained from the New York City water supply system which is taken from a reservoir greater than 8 miles from the site. There were no known domestic groundwater users within a 1/2-mile radius of the site, and the closest potential potable water source is the Sheldrake Reservoir, located approximately 1.5 miles upstream from the site. At the time of the study, the Sheldrake Reservoir was used as an emergency water source only.

2.2 Climate

The climate in Westchester County is characterized as humid-continental and, thus, exhibits highly variable weather systems and strong seasonal contrasts. Continental air masses provide the predominant influence on Westchester County weather systems, although maritime air masses also influence the area and provide milder temperatures than continental areas located to the west along the same latitude. Average winter temperatures vary from 20 to 30 degrees Fahrenheit, whereas summer temperatures generally average in the 80 degree Fahrenheit range. Average precipitation is on the order of 45 inches per year.

2.3 Surface Water Hydrology and Site Drainage

Surface water at the former EMCA site drains into the Sheldrake River drainage basin of the lower Long Island Sound watershed. Sheldrake waters discharge into the Mamaroneck River and in turn to the Atlantic Ocean at Mamaroneck Harbor. The Sheldrake River is classified as a NYSDEC "Class C" water body as per Title 6 Parts 701 (Article 9) and 935 (Article18) of the New York Code of Rules and Regulations (NYCRR). This classification indicates these waters are suitable for fishing and primary and secondary contact recreation, although other factors may limit the use for these purposes. Surface drainage is primarily controlled by a storm sewer system that likely conveys stormwater to the Sheldrake River via subsurface pipes.

2.4 Geology and Hydrogeology

Geologic conditions at the site are characterized by unconsolidated deposits composed predominantly of stratified medium to fine sand with localized beds of coarse sand, gravel, silt, and clay. The deepest site boring was advanced to 32 feet below ground surface and bedrock is assumed at an approximate depth of 40 feet [as per *Risk Assessment, Former EMCA Site* (WCC 1989b)]. Groundwater conditions consist of a water table aquifer encountered at a depth of approximately 6 feet below ground surface. Groundwater generally flows to the northwest towards the Sheldrake River.

As shown in Figure 8, there was a considerable mounding effect on the water table in the vicinity of monitoring well GZ-03 in October 1999. This mound is believed to be the result of roof drains from surrounding buildings that discharge in the vicinity of this well. This mounding effect is likely limited to the uppermost water table; deeper groundwater flow is likely conveyed in a more direct northwesterly course towards the Sheldrake River. The mounding was significantly less pronounced during the July 2000 monitoring event (Figure 9).

3.0 SITE INVESTIGATIONS

URS personnel mobilized to the site twice, once during the week of October 4, 1999, and again during the week of July 10, 2000. Field investigations were performed to meet the objectives of this RI, in accordance with the approved work plans. Remedial investigation field activities included conducting: soil gas sampling, surface soil sampling, well and piezometer installation, well development, groundwater sampling, surveying and obtaining groundwater level data. During field investigation activities, representatives from NYSDEC and Rohm and Haas Company were onsite full time, and a NYSDOH representative was onsite part time during the October 1999 event. Details and procedures pertaining to each investigated medium are described in the following subsections.

3.1 Soil Gas Sampling

Soil gas sampling consisted of screening total organic vapor concentrations in the field and collecting soil gas samples for subsequent laboratory analysis. A summary of the soil gas monitoring program is provided in the following sections.

3.1.1 Soil Gas FID Screening

Soil gas concentrations were measured in the field using a flame ionization detector (FID) at the locations listed in Table 1 and shown in Figure 5. The FID readings were taken directly from a soil gas sampling probe that was driven a few feet into vadose zone soils. Soil gas readings were conducted using the methods outlined in the work plan, except that the probe was mechanically driven to depth using a Geoprobe rig, rather than manually driven to the stated depth. At each location, the probe was directly connected to a FID, and direct soil gas readings were recorded. As per the work plan, soil gas FID readings for the October 1999 event should have been collected at all five locations. The FID used for evaluating soil gas at SG-02 and SG-05 malfunctioned, therefore, no usable FID data was obtained at these locations. However, an analytical soil gas sample was collected as SG-05, and FID soil screening and groundwater analysis was conducted at MW-02 (adjacent to the SG-02 location). The readings collected at locations SG-01, SG-03, SG-04, SG-06 and SG-07 were taken with a separate FID. These readings were recorded in accordance with the work plan and are considered to be accurate.

3.1.2 Analytical Soil Gas Sampling

URS obtained soil gas (SUMMA canister) samples for subsequent laboratory analysis from location SG-03,SG-05, SG-06 and SG-07. In addition, an ambient air sample was collected for laboratory analysis near SG-04 during the October 1999 event, and an ambient air sample was collected near SG-07 during the July 2000 event. The samples were collected in accordance with the work plan, except for the following deviations:

- The collection rate used for obtaining soil gas was decreased to 0.2 liter/minute as per NYSDEC request (each SUMMA canister took approximately 30 minutes to fill)
- The collection rate used for obtaining ambient air during the October 1999 event was less than 0.1 liter/minute due to a faulty flow regulator (sample quality was unaffected)
- The samples were analyzed by Air Toxics Ltd. of Folsom, California using Method TO14 protocols.

3.2 Surface Soil Sampling

One grab soil sample was collected from 0 to 6 inches below the existing asphalt and sub-base layers at location SS-01 (Figure 6) using a Geoprobe macro-sampler. In addition, one composite sample was collected from surface soils 0 to 6 inches below turf from the grass area near the corner of Fayette and Ogden Avenues. The soil samples were analyzed for barium, copper, lead, silver, and zinc. Surface soil sample locations are shown in Figure 6 and in Table 2.

3.3 NYSDOH Air Sampling

On July 11, 2000, the NYSDOH collected ambient air samples at two houses near the former EMCA Site (530 Fayette Avenue and 614 Center Avenue) and within the existing Cablevision of Westchester facility located on the site. NYSDEC has provided URS and Rohm and Haas with the Freon 113 results from this sampling effort. These data are provided in Appendix I.

3.4 Groundwater Investigations

The groundwater investigation consisted of installing five Geoprobe monitoring wells, two temporary piezometers, and collecting two rounds of samples from new and existing wells for subsequent laboratory analysis.

3.4.1 Monitoring Well Installation and Development

Five Geoprobe wells (mill-slot well points) were installed to replace former wells (that could no longer be found) and expand the area of investigation. Well locations are shown in Figure 2. It should be noted, former wells GZ-02 and GZ-05 were not replaced, since these locations were not needed to adequately characterize site contamination. The replacement wells were constructed in small diameter boreholes advanced using a Geoprobe. A field geologist provided a soil log for each new well location using visual classification in accordance with the Unified Soil Classification System. Upon boring completion, 1-inch inside diameter (ID) Schedule 40 polyvinyl chloride (PVC) monitoring wells were installed in the open borehole to the same approximate depths as the former site wells. The wells were sealed with bentonite grout and steel surface casings with locking caps were installed. Boring logs and well construction diagrams are provided in Appendix D.

Prior to each sampling event, each monitoring well (including the five new temporary Geoprobe monitoring wells and the two existing monitoring wells) was developed until the discharge water was relatively sediment free and the water quality parameters (pH, temperature, and specific conductivity) stabilized. Development was conducted in accordance with the work plan, except that groundwater was evacuated by bailing rather than pumping. Well development logs are provided in Appendix E.

3.4.2 Piezometer Installation

Two temporary piezometers—used for monitoring groundwater elevation—were installed at the locations shown in Figure 2. They were installed in accordance with the work plan, except that 1-inch well riser pipe and screen were used rather than the specified 3/4-inch well pipe (the change was made since 3/4-inch well pipe was not readily available). The piezometers were developed using the same procedures as site monitoring wells. Both

piezometers were pulled and abandoned in accordance with the work plan following the October 1999 sampling event.

3.4.3 Groundwater Sampling

3.4.3.1 October 1999 Groundwater Sampling

Groundwater samples were collected from six monitoring wells (GZ-03, GZ-06, and MW-01 through MW-04) on October 7, 1999. All wells were purged (using low flow purging procedures) in accordance with the work plan prior to obtaining samples. Water quality parameters were measured during well purging and sampling. In addition, one deep sample (GRAB-01 from 29 to 31 feet below ground surface) was collected adjacent to MW-04 using a temporary Geoprobe screen point sampler. Each groundwater sample was analyzed for Target Compound List volatiles, Freon 113, and tentatively identified compounds. Two wells (MW-01 and MW-04) also were analyzed for barium, copper, lead, silver, and zinc. The October 1999 groundwater sample summary is shown in Table 3, and well purging and sampling logs are presented in Appendix E.

During field sampling, the NYSDEC collected split samples from wells MW-01, MW-03, and MW-04. The NYSDEC contracted a separate laboratory for the split sample data analysis, these results are presented in Appendix H.

3.4.3.2 July 2000 Groundwater Sampling

Groundwater samples were collected from five monitoring wells (GZ-06, MW-01, MW-02, MW-03, and MW-05) on July 13, 2000. The wells were purged in accordance with the Field Investigation Plan (as amended May 30, 2000). The groundwater samples were analyzed for Target Compound List volatiles, Freon 113, and tentatively identified compounds. The July 2000 groundwater sample summary is shown in Table 3, and well purging and sampling logs are presented in Appendix E.

3.5 Data Usability

URS conducted a review of data quality in accordance with the document entitled, *Guidance for the Development of Data Usability Summary Reports* (NYSDEC 1999) and the approved work plan. Data Usability Summary Reports for the October 1999 and July 2000 events are provided in Appendix C.1 and C.2 respectively.

3.6 Survey

An engineering survey was conducted to provide horizontal and vertical control of the new Geoprobe wells and piezometers. For the well and piezometer locations, the vertical elevations were recorded at the ground surface adjacent to the wells and on the north side of the top of well risers (the PVC well pipes). Existing wells GZ-3, GZ-6, and GZ-9 were also surveyed. In addition, horizontal/vertical control was established for four points along the Sheldrake River for recording surface water elevations.

The northings and eastings identified for wells, piezometers, and stream gauges were referenced to an assumed coordinate system that is exclusive to this site. Similarly, reported elevations were referenced to the elevation of the finish floor in a doorway at the northern Cablevision of Westchester building corner. The datum for this benchmark was assumed at 100.00 feet. Refer to Table 4 for a summary of survey results.

4.0 NATURE AND EXTENT OF CONTAMINATION

This section discusses the analytical data as it pertains to soil gas, surface soil, and groundwater samples collected during the RI. It characterizes the nature and extent of site contaminants, and compares soil and aqueous contaminant concentrations to applicable regulatory criteria.

Groundwater sample analytical results were compared to the NYSDEC Division of Water's "Ambient Water Quality Standards and Guidance Values and Groundwater Effluent Limitations," *Technical and Operational Guidance Series* (TOGS) 1.1.1, (NYSDEC 2000). The ambient water quality standards and guidance values are derived from Article 17 of the Environmental Conservation Law and Title 6 of the New York Code of Rules and Regulations (NYCRR) Parts 700-706, "Water Quality Regulations." Standards and guidance values are ambient water quality values that are established to protect the state's waters. Groundwater Class GA criteria were used to evaluate groundwater analytical results.

Soil sample analytical results were compared to the standards, criteria, and guidance values (SCGs) in TAGM 4046 (NYSDEC 1994). As indicated on the attached tables, some of the inorganics (metals) analyzed at this site do not have SCGs. For these inorganic parameters, soil criteria are based upon SCGs, where available, or the range of soil concentrations occurring naturally in Eastern United States soils. For inorganic parameters, the results of the single offsite soil sample, SS-02, is considered representative of site background conditions.

There are no New York State guidance values for soil gas samples, although, as a conservative approach, the detected soil gas concentrations have been compared to ambient air quality standards reported in the DAR-1 (Air Guide-1) Annual and Short Term Guidance Concentrations (NYSDEC 2000). This document provides guideline concentrations for toxic ambient air contaminants that are present in ambient air. As such, since soil gas would be substantially diluted upon release to ambient conditions, this standard is considered an exceptionally stringent criteria for soil gas comparisons.

Soil gas laboratory analyses were performed by Air Toxics Ltd. in Folsom, California. The Data Usability Summary Report, along with the validated analytical data, are presented in Appendix C. Sample analytical results are discussed below.

4.1 Soil Gas Analytical Results

Soil gas concentrations were measured in Geoprobe borings at the locations shown in Figure 5. A high FID reading was recorded at soil gas probe SG-01 (Figure 5), which is offsite and upgradient of the site with respect to groundwater flow. This corroborates previous reports which indicate there may be an offsite, upgradient source of contamination to the south or southeast of the site.

Soil gas samples were collected for laboratory analysis of volatile organics, Freon 113, and tentatively identified compounds (TICs). Samples were collected from locations SG-03 and SG-05 during the October 1999 sampling event and from SG-06 and SG-07 during the July 2000 sampling event. Ambient air samples were collected during each sampling event near the soil gas probe locations.

Samples SG-03 and SG-05 both exhibited quantifiable concentrations of Freon 113, although, Freon 113 was not detected at SG-06 and SG-07. As shown on Figure 5 and Table 5, several other compounds (including chlorinated hydrocarbons and BTEX compounds) were detected in soil gas. The ambient air samples exhibited only low levels of acetone (a common laboratory contaminant) and chloromethane (Table 5).

The soil gas samples also were evaluated to determine whether soil gas is a potential contaminant pathway. However, there are no NYSDEC soil gas guidance values available for evaluating whether these results are of concern. Therefore, as a first approximation, the soil gas results were compared to New York State Air Guide concentrations for ambient air (Table 5). The guideline concentrations provide a very conservative criteria for this comparison. A review of Table 5 shows that benzene (at SG-05, SG-06 and SG-07) and chloroform, methylene chloride, and tetrachloroethene (at SG-06) exceeded the New York State Air Guide criteria.

The detected soil gas concentrations for Freon 113 are believed to be a minor concern, since they are well below the New York State air guidelines. As such, soil gas should not be considered a medium of concern at this site. The remaining compounds detectected in soil gas are thought to be related to off-site contamination.

4.2 NYSDOH Ambient Air Results

Data collected by NYSDOH on July 11, 2000 indicates the concentrations of Freon 113 are exceptionally low in the residential structures and business facilities on and adjacent to the site. NYSDOH's data provides further evidence that soil gas, which could theoretically migrate to off-site buildings, is not a medium of concern.

4.3 Surface Soil Analytical Results

Two surface soil samples were analyzed for barium, copper, lead, silver, and zinc. One of these samples (SS-02) is considered an offsite "background" sample. The other sample (SS-01) was taken from a location near the center of the site in an area that was actively used during EMCA's former industrial activities. Refer to Table 2 and Figure 6 for results of the surface soil analytical sampling efforts.

Both samples had comparable results except for somewhat elevated concentrations of lead at the onsite location (SS-01). The lead result at SS-01 was 445 ppm, which is well within the range of concentrations which would be considered "normal" for such an industrialized area. As stated in the NYSDEC TAGM - Revised April 1995 "Background levels for lead vary widely. Average background levels in metropolitan or suburban areas near highways are much higher and typically range from 200-500 ppm. The USEPA's Interim Lead Hazard Guidance (July 14, 1994) establishes a residential screening level of 400 ppm." As such, based on these results, and given that the highest lead value was from below a paved area, surface soils should not be considered a primary medium of concern at this site.

4.4 Groundwater Analytical Results

4.4.1 October 1999 Groundwater Data

Groundwater samples were collected from two existing overburden monitoring wells (GZ-03 and GZ-06), four newly-installed overburden monitoring wells (MW-01 through MW-04), and one Geoprobe sample collected in the vicinity of monitoring well MW-04 (but deeper). Based on the northwesterly direction of groundwater flow, MW-01 and GZ-06 are considered upgradient wells (Figure 8). Table 3 summarizes the detected analytes and identifies detections above New York State Class GA groundwater standards, and Figure 10 shows a summary and location of these exceedances.

As shown in Figure 10, the following organic compounds were detected at concentrations exceeding Class GA standards: benzene, 1,2-dichloroethene (total), tetrachloroethene, trichloroethene, Freon 113, and vinyl chloride. Except for Freon 113, the highest concentration of each of these compounds was in upgradient well MW-01. The highest concentration of Freon 113 was at monitoring well MW-03. This indicates that there is an onsite source only for Freon 113; all other contaminants appear to have migrated onto the former EMCA site from an upgradient source. A cursory review of spill records conducted as part of this RI revealed several past offsite petroleum-related spills recorded by NYSDEC (Appendix G). There is no indication of past chlorinated hydrocarbon spills at this time.

Five metals (barium, copper, lead, silver, and zinc) were analyzed from monitoring wells MW-01 and MW-04. Both unfiltered and filtered samples were collected. All metals concentrations were below Class GA standards and, therefore, are not considered to be a concern at this site. It should be noted, NYSDEC representatives collected split samples from wells MW-01, MW-03 and MW-04. A comparison of URS and NYSDEC sample results is provided in Appendix H. In general, the samples are within a reasonable range of variation, except for Freon 113 results from MW-03. NYSDEC's result for this compound is approximately one order of magnitude lower than URS's result. However, NYSDEC's laboratory did not specifically analyze for this compound, but rather it was detected as a TIC. Therefore, NYSDEC's result is

an estimate; the URS value has been verified through quality assurance/quality control procedures and is considered to be the more accurate value.

4.4.2 July 2000 Groundwater Data

Groundwater samples were collected from six wells (GZ-06, MW-01, MW-02, MW-03, MW-04 and MW-05) during the July 2000 sampling event. Sample results are presented in Table 3 and in Figure 11. As shown in Figure 11, the following compounds exceeded the Class GA standards during the July 2000 sampling event: acetone, benzene, chloroform, Freon 113, 1,2-dichloroethene, tetrachloroethene, trichloroethene, and vinyl chloride. In general, the data indicates similar compounds as detected in the past, although there are some notable differences between the October 1999 and July 2000 sampling events. These include:

- Acetone was detected at wells GZ-06, MW-02, and MW-03
- Chloroform was detected at wells MW-02 and MW-03 and exceeded Class GA standards at well GZ-06
- Freon 113 levels increased at monitoring well GZ-06

Acetone (a common laboratory contaminant) has been detected at the site in the past. However, the current acetone detections are suspect for two reasons. First, acetone is relatively soluble in water and highly volatile. Therefore, it is doubtful that acetone has remained onsite (virtually undetected) for more than 12 years. Second, the presence of Freon 113 in groundwater interfered with the laboratory's ability to verify the presence of acetone. As stated in the *Data Usability Summary Report*, (Appendix C), "the sample spectra did not conclusively illustrate it's (i.e., acetone's) presence."

Chloroform, has been detected at the site previously, although it was not present during the October 1999 sampling event. Chloroform is a breakdown product of chlorinated hydrocarbons, and therefore, it is most likely related to the plume of contamination migrating onsite from an upgradient source.

At well GZ-06, Freon 113 levels increased from 49 ug/l in October 1999 to 900 ug/l in July 2000. The reason for this increase may be related to a variety of factors such as the intake depth of the sampling device, or changes in physical well parameters. Well GZ-06 does have a history of high Freon 113. A concentration of 1274 ug/l was detected in May 1988, although until now, concentrations at this well were steadily declining.

4.4.3 Summary of Groundwater Analyses

The level of concern with regard to groundwater is considered minimal since there is little risk of human contact. For example:

- There is no municipal, domestic, or industrial use of groundwater within ½ mile of the site
- The nearest municipal water supply relying on groundwater is the City of White Plains – approximately 9.5 miles from the site
- The Sheldrake River is not classified as a source of drinking water within 1.5 miles of the site
- The closest potable surface water supply reservoir, Lake Sheldrake, is located 1.5 miles upstream of the site and is used only as an emergency source of drinking water.

Groundwater is, however, a potential transport mechanism for the offsite migration of contamination and, therefore, further discussion regarding this medium is provided in Section 5.

5.0 CONTAMINANT FATE AND TRANSPORT

5.1 Groundwater Fate and Transport

The EMCA site was formerly a manufacturing facility for high conductivity precious metal paste used in circuits by the electronics industry. The remedial investigations conducted at this site were designed to evaluate potential environmental concerns related to this industry and assess their potential impact to the community. Towards this end, four rounds of groundwater samples were collected (May 1988, March 1989, October 1999 and July 2000). These samples were analyzed for volatiles, Freon 113 and filtered and unfiltered metals.

Based on these evaluations, there is no appreciable metals contamination in groundwater at the site. However, volatile contaminants and Freon 113 were detected in groundwater above the NYSDEC Class GA drinking water standards. The only compound thought to be related to the former manufacturing process at the EMCA facility is Freon 113. The remaining compounds detected in groundwater are believed to be migrating onto the site from other industrial facilities in the area. There is a potential for offsite migration of groundwater containing Freon 113. Therefore, groundwater is considered a potential media of concern with respect to site contamination.

Migration theoretically could result in direct discharge of contaminated groundwater to the Sheldrake River or provide a source for volatilization and secondary transport of gases through unsaturated soil. Both of these transport mechanisms were evaluated in a previous Risk Assessment which concluded that there was not a significant risk to human health or the environment. Recent air quality analytical sampling of Freon 113 conducted by the NYSDOH in area homes and the Cablevision of Westchester facility indicates that Freon 113 is not a health concern at these locations. Therefore, NYSDOH's data further validates the conclusions of the previous Risk Assessment.

The primary mechanisms for contaminant transport via groundwater are advection, dispersion, and diffusion. The extent of travel depends on the flow of the groundwater and on the contaminant properties. The VOCs which have been identified at this site can be considered relatively mobile, although, given that ten years has passed since the site was actively used for industrial processes, it is plausible that contaminant transport has reached static or near static conditions for Freon 113. This is evidenced by low Freon 113 concentrations at downgradient well locations.

Figures 12 and 13 provide a conceptual model of groundwater contaminant plumes based on groundwater samples and groundwater elevation data from October 1999 and July 2000 respectively. As shown in Figures 12 and 13, it appears there are two separate plumes. The first plume, consisting of Freon 113 (identified as 1,1,2-trichlorotrifluoroethane on the Figures), is located to the northeastern portion of the site adjacent to Ogden Avenue. The second plume, consisting of chlorinated hydrocarbons and benzene, trends north/south across the site and appears to be migrating onto the site from an upgradient source.

In general, the Freon 113 plume has decreased in concentration since samples were collected in 1988 and 1989, except in the vicinity of MW-03 and GZ-06. Significantly lower concentrations at the downgradient monitoring wells (MW-04 and MW-05) indicate that it is unlikely that the Freon 113 plume extends beyond Fayette Avenue. It is also noted that Freon 113 contamination remains relatively shallow, as confirmed by the absence of Freon 113 at Geoprobe sample location GRAB-01. Based on October 1999 and July 2000 results, it is unlikely that Freon 113 discharges to the Sheldrake River (approximately 200 feet downgradient of the site).

Based on the results of the soil gas sampling, it is evident that volatilization of Freon 113 in groundwater is affecting the unsaturated soil zone. However, this soil gas is not present at levels of concern even in the area of MW-03, where the highest groundwater levels were detected. The soil gas results from SG-03 (adjacent to MW-03) show a concentration of 3,300 parts per billion by volume (ppbv) (or 25,654 µg/m3). This value is well below the assumed value used in the previous risk assessment (18,266 ppbv or 142,000 µg/m3) which indicates there is no risk from Freon 113. Soil gas samples taken in July 2000 on the north side of Ogden Avenue (SG-06 and SG-07) show that Freon 113 is not present in soil gas in this area. This

indicates that Freon 113 is not migrating in the gaseous state through unsaturated soils towards residences located north of the former EMCA site. All soil gas samples analyzed for Freon 113 were below New York State Air Guide criteria (Table 5).

This RI was conducted to characterize subsurface contamination at the Former EMCA Site. Through this effort, it has been determined that the only groundwater contaminant related to the former EMCA process is Freon 113. Although there is a remnant plume of Freon 113 contaminated groundwater at the site (approximately two-tenths of an acre in size), the potential exposure and potential impact to human and environmental receptors is minimal. This is evidenced by:

- Groundwater samples show very low levels of Freon 113 in groundwater at the downgradient site boundary
- Soil gas samples show that secondary volatilization of groundwater contamination is low risk
- Air samples collected by NYSDOH in area homes and the Cablevision of Westchester facility indicate Freon is not a risk to residents or area workers

This RI was also conducted to evaluate other groundwater contamination at the site and various volatile organics, i.e. chlorinated hydrocarbons and benzene, were identified. As previously noted, the data indicates these compounds are migrating onto the EMCA site from upgradient sources. The chlorinated hydrocarbon/benzene plume appears to be taking a deeper course beneath the site (as evidenced by benzene detected at GRAB-01 but not at MW-04), although this plume co-exists with the Freon 113 plume in the vicinity of MW-02 and MW-03. Based on high FID screening levels at upgradient soil gas screening location SG-01, it appears that volatilization from groundwater to soil gas potentially could be a route of migration for chlorinated hydrocarbons and benzene.

5.2 Soil Fate and Transport

Soils analyses were conducted to evaluate volatiles, Freon 113, and metals at various onsite locations. The volatile and Freon 113 concentrations detected onsite were compared to NY State standards, criteria, and guidance values (SCGs) provided in TAGM 4046, and none of the detected compounds exceeded the guidance levels. The metals detections were compared to the NYSDEC TAGM guidance and to USEPA's guidance and, in general, metals concentrations were considered "normal" for industrial areas.

Since soil at the site is covered by structures or pavement, there is very little potential for offsite transport for soil contamination. Furthermore, the level of soil contamination detected at the site does not warrant remedial action.

6.0 PRELIMINARY REMEDIAL ALTERNATIVES

Site data indicates low risk with respect to the Freon 113 in groundwater. However, because there is a small area where Class GA groundwater standards are exceeded, the NYSDEC suggested that a feasibility study be considered. Accordingly, URS has prepared the following preliminary list of mechanisms that could be used for destroying and/or removing Freon 113.

Monitored Natural Attenuation: Under this alternative, contaminated groundwater would remain in place and be sampled periodically. Groundwater monitoring would verify that the Freon 113 contamination does not spread away from the site, and that it decreases with time, as natural attenuation occurs. Deed restrictions on the groundwater use may be required to prevent future human exposure to site contaminants, until remediation would be complete. Remediation under this alternative can last for a long period, however contaminants will be efficiently removed from the groundwater, without impacting offsite users. Should the contaminant plume start migrating downgradient, another treatment technology would then need to be implemented.

Hydrogen Release Compound (HRC): This is an in-situ technology that offers a passive, effective, and low-cost approach to rapidly remediating groundwater contaminated with chlorinated solvents. It includes the introduction into the ground of a patented polylactate ester, which when hydrated, slowly releases lactic acid in a multi-step process. During this process, chlorinated compounds and their derivatives degrade. This technology would be appropriate for the groundwater contamination at the former EMCA site.

Air Sparging: This is an in-situ remedial technology that rapidly and efficiently reduces the concentrations of volatile chemicals that are dissolved in the groundwater. This technology involves the injection of chemical-free air into the subsurface, enabling dissolved volatile chemicals to transfer from the liquid phase to the vapor phase. The air is then vented through the unsaturated zone from which it is captured by a vacuum extraction process. The extracted contaminant-laden air passes through a treatment process, such as an activated carbon adsorption unit, which captures the contaminants, before they are released to the atmosphere. However, the

vacuum extraction process may cause excessive noise. Noise issues will need to be considered for this site due to the nearby homes and businesses.

Bioremediation: This is an in-situ technology, which encourages the growth of indigenous microorganisms by adding nutrients to the subsurface, and thereby, enhancing biodegradation of organic constituents in the saturated zone. Bioremediation can effectively degrade organic chemicals that are dissolved in the groundwater. There is aerobic (oxygen respiration), anoxic (nitrogen respiration), and anaerobic (non-oxygen respiration) bioremediation for treating chlorinated and non-chlorinated chemicals. At the EMCA site, where Freon 113 is the site-related contaminant, anoxic and/or anaerobic bioremediation would be appropriate.

7.0 SUMMARY AND RECOMMENDATIONS

Based on this RI, two overlapping plumes of contamination were found to remain at the former EMCA site. The first plume consists of Freon 113, is relatively shallow, and appears to be confined to the northeastern portion of the site. The second plume contains chlorinated hydrocarbons and benzene and appears to have migrated onto the former EMCA site from an offsite upgradient source.

The Freon 113 plume has decreased over the past ten years at all locations except MW-03 and possibly GZ-06. However, MW-03 and GZ-06 have decreased slightly since the initial sampling round in 1988. Given the results of this RI, the Freon 113 contamination at the site is considered less of a problem today than when previous investigations were conducted during the late 1980s.

When Rohm and Haas initiated site investigations during the late 1980's, two rounds of site sampling were conducted, and that data was used to evaluate health risk concerns to area residents and workers. Based on the initial 1980's data it was determined that there was no significant risk to human health or the environment with respect to Freon 113 contamination (the only site contaminant related to manufacturing at the former EMCA site) (WCC 1989b). Since that time, Rohm and Haas has conducted two additional rounds of investigations consisting of soil sampling, groundwater sampling, groundwater level evaluations, surface water level evaluations, and soil gas sampling. These recent data indicate the conclusions made during the late 1980's are still valid – there is still no significant risk to human health or the environment at the site. This conclusion is augmented by NYSDOH's air sampling results from residential homes and the Cablevision of Westchester facility that verify there is low risk to human health due to Freon 113 within these structures.

Even though there is no significant risk associated with Freon 113, there is a remnant groundwater plume onsite with concentrations above the Class GA standards. As such, NYSDEC requested that Rohm and Haas investigate preliminary remedial alternatives for the remnant plume. The preliminary remedial alternatives have been provided as a platform for Rohm and Haas and NYSDEC to discuss possible future activities at the former EMCA site.

I. INTRODUCTION

A. Site Background

During the property transfer of the former EMCA site to United Artists Columbia Cablevision (UACC), now TCI Cable of Westchester, Inc. (TCI Cable), a preliminary site assessment and an assessment of subsurface conditions was conducted. These assessments indicated the presence of 1,1,2-trichloro-1,2,2-trifluoroethane (Freon 113) and several other volatile organic compounds in the soil and ground water. Woodward-Clyde Consultants (WCC) conducted a risk assessment to evaluate the possibility of any impact from the migration of chemicals in the soil and ground water. Based on their evaluation WCC concluded that the soil and ground water contaminants did not demonstrate a risk to human health or the environment.

B. Purpose of Conducting Indoor Air Sampling

To address the concerns of current occupants of the TCI Cable building that the previously identified chemicals may nonetheless present a health risk, indoor air sampling was conducted. The air sampling protocol was designed to determine if the previously identified chemicals in soil and ground water are migrating into the workplace environment.

ENVIRON reviewed the soil and ground water data presented in the WCC risk assessment and identified 16 compounds (Table 1) at levels above the detection limit. The indoor air sampling protocol was developed to analyze for these 16 compounds.

II. SAMPLING METHODOLOGY

A. Sampling Locations

A site walk-through was conducted prior to collecting the indoor air samples. Because of the extreme sensitivity of the analytic procedures employed in the investigation, an effort was made to isolate potential minor sources of the chemical constituents prior to the indoor air sampling. These minor sources would include routine cleaning fluids, solvents, or "dust-off" propellent-containing spray cans. Prior to collecting the indoor air samples, the locations of sumps and drains were identified and the proposed sampling locations were finalized.

Eight indoor locations (four on each floor) were identified. The first floor locations were selected to represent potential areas where soil and ground water chemicals could enter the building floor. Considerations were given to areas with potential impact from sumps, drains and elevator shafts. These first floor locations include Head End Room, Men's Room, Utility Room and outside the elevator. The second floor samples were selected to represent the indoor air quality of the TCI Cable building. The second floor locations include the Lunch Room, hallway adjacent to Human Resources, Marketing Office and hallway near the elevator. Indoor air sampling locations are indicated on the TCI Cable building floor plans, provided as Attachment A. Two outdoor samples were collected from the two air intake vents located on the roof of the building. The outdoor samples were collected to represent the ambient outdoor air quality.

B. Sampling Methodology

All air samples were collected in stainless steel SUMMA canisters by an experienced certified industrial hygienist (CIH). Since the indoor atmospheric environment in the TCI Cable building is homogeneous, with no specific air contaminant source or operation in the building, the indoor air samples were collected as grab samples. The canisters used to

collect the outdoor samples were equipped with a precalibrated flow controller such that the outdoor air samples represented a time-weighted average sample, obtained during the time period which the indoor air samples were collected (i.e., about two hours). The direction of the wind socks were noted at the initiation and termination of the outdoor air sampling. Photographs of outdoor sampling methodology, documenting wind direction, are provided in Appendix B.

C. Additional Parameters

At each sampling location, temperature and relative humidity readings were recorded. Carbon dioxide measurements (using Draeger tubes) were taken at select locations. Field data and report of air sample collection, prepared by the CIH, are provided as Appendix C.

D. Quality Assurance/Quality Control

A chain of custody record analytical services request was completed and submitted to the analytical laboratory with the 10 air samples. A copy of the chain-of-custody record is provided as Appendix D. The samples were received and processed by the analytical laboratory the day following the sample collection.

III. ANALYTICAL METHODOLOGY

The air samples were analyzed by combined gas chromatography/mass spectrometry (GC/MS) for 16 volatile organic compounds. The analyses were performed according to the methodology outlined in USEPA Method TO-14 from the Compendium of Methods for the Determination of Toxic Organic Compounds in Ambient Air (USEPA 1988). This methodology allowed positive identification of the 16 target compounds and provided detection limits in the parts per billion (ppb) range.

Quality assurance/quality control procedures included analysis of a laboratory method blank and a laboratory duplicate. The results of the laboratory method blank and the laboratory duplicate were within the acceptable range.

IV. INTERPRETATION OF RESULTS

Of the 16 chemicals previously identified in the soil and ground water, nine were detected at low levels in both the indoor and outdoor air. This is an expected result because all of these chemicals are common air contaminants and are frequently detected at these levels. Chloroform was detected at trace concentrations in two indoor air samples and was not detected in the outdoor air. Based on the sampling locations where chloroform was detected (i.e., Men's Room and Utility Room) the source of the chloroform was probably due to the presence of chlorinated drinking water in these areas.

The chemical concentrations were slightly higher in the indoor air samples than the outdoor air samples. This is not atypical and most likely due to air recycling, and other possible sources such as routine cleaning use of these chemicals within the building. Specifically, some of these common chemicals are present in cleaning solvents used on site and Freon 113 is used in the maintenance of the video tape equipment.

A chemical-specific comparison of the average indoor air concentration of the nine chemicals to reference levels is provided in Figures 1 through 9. Reference levels used for comparison were obtained from the National Air Toxics Information Clearinghouse (NATICH) database, Agency for Toxic Substance Disease Registry (ATSDR), Occupational Safety and Health Administration (OSHA), and the United States Environmental Protection Agency (USEPA) Total Exposure Assessment Methodology (TEAM) Study.

The NATICH database provides state-specific acceptable ambient air concentration guidelines or standards. The nine compounds detected in indoor air were compared to the acceptable ambient concentration guidelines/standards for New York State, when available. The levels detected in the TCI Cable air sampling were well below any ambient air quality guidelines proposed by the State of New York. Ambient air background concentrations (either as ranges or maximum reported values) were compiled from the ATSDR toxicological profiles on select chemicals, when available. These ambient concentrations

were compared to levels detected in the TCI Cable indoor air. The air concentrations of the 9 target compounds detected in indoor air were also compared to the OSHA-Permissible Exposure Levels (PELs). The OSHA-PELs are time-weighted average concentrations that must not be exceeded during any 8-hour work shift of a 40-hour work-week. Indoor air sample results indicate that all target compounds were at least 300 times below the OSHA-PEL.

Air concentrations detected on-site were compared to ambient indoor air concentrations reported in the USEPA TEAM study, when available. The TEAM study reported average indoor air concentrations for trichloroethylene; 1,1,1-trichloroethane; tetrachloroethylene; and ethylbenzene. A comparison of the indoor air concentrations in the TCI Cable building were all below the ambient indoor air concentrations reported in the TEAM study.

A summary of results of air sampling at TCI Cable is provided in Table 2, along with average indoor and outdoor air concentrations. The analytical laboratory report is provided as Appendix E.

Figure Legend for Figures 1 through 9

Average Indoor Conc.	-	Average indoor air concentration for the eight indoor air samples collected in the TCI Cable building. The maximum concentration detected in the TCI Cable building are indicated by the arrow and dotted line.
Average Outdoor Conc.	-	Average outdoor air concentration for the two outdoor samples collected from the roof of the TCI Cable building.
USEPA TEAM Study Ave. Indoor Conc.	-	These values represent weighted mean personal air concentrations for select chemicals collected from 110,000 Elizabeth-Bayonne residents during the summer of 1982 (USEPA TEAM Study, Table 21). United States Environmental Protection Agency (USEPA) Total Exposure Assessment Methodology (TEAM) Study was designed to develop methods to measure individual total exposure (exposure through food, air and water) and resulting body burden of toxic and carcinogenic chemicals; and to apply these methods with a probability-based sampling framework to estimate the exposures and body burdens of urban populations in several U.S. cities.
ATSDR Background Air Conc.	-	Ambient air concentrations the general population may be exposed to provided by the Agency for Toxic Substance Disease Registry (ATSDR). These values may be reported as ranges or maximum values not expected to be exceeded in any background area.
NATICH New York	-	New York State acceptable ambient concentration guidelines as provided in the National Air Toxics Information Clearinghouse (NATICH) database.
OSHA PEL	-	The Occupational Safety and Health Administration (OSHA) Permissible Exposure Levels (PELs) are time-weighted average

concentrations that must not be exceeded during any 8-hour work shift of a 40-hour work week.

ppb - Parts per billion.

V. CONCLUSIONS

The indoor air sampling results do not indicate any evidence of chemicals previously identified in the soil and ground water beneath the TCI Cable building migrating into the indoor air of the building. Of the 16 target compounds, nine were detected at low levels and seven were not detected with detection limits in the 1-4 ppb range. The concentrations of the nine chemicals detected in indoor air were slightly higher than the outdoor air, probably due to air recycling. The chemicals identified in the indoor air are common indoor air contaminants and are commonly present in the environment. Other possible sources of these chemicals include routine use within the building, such as in cleaning fluids and spray propellants.

A comparison of the indoor air sampling results to specific reference levels showed that all chemicals were well below the acceptable Ambient Air Quality guidelines proposed by the State of New York, and are at least 300 times below the occupational OSHA permissible exposure limit (PEL) mandated by OSHA.

Based on the indoor air sampling results, there is no evidence to suggest that the levels of chemicals detected would produce any adverse health effects to the occupants of the TCI Cable building.

Air Sampling at UACC in Mamaroneck, NY

On Wednesday, August 19, 1992, a certified industrial hygienist form Compliance Management, Incorporated, collected ten air samples at the United Artists Columbia Cable System (UACC) facility at 609 Center Avenue, Mamoroneck, New York. Eight of the samples were grab samples taken from various locations throughout the building; the remaining two samples were two hour time integrated samples collected outside of the building, on the roof, near two of the fresh air intakes for the building's HVAC system. The samples were collected in pre-evacuated, 6 liter, SUMMA canisters. The canisters were supplied by Performance Analytical Incorporated of Canoga Park, California and were returned to them for subsequent analysis. In addition, temperature and relative humidity were determined at each sampling point. Furthermore, carbon dioxide levels were determined at selected locations during the sampling. A summary of field data and sampling locations is presented in Table 1.

During the collection of the samples of outdoor air, the flow into the canisters was restricted by a flow controlled which allowed for the collection of a two hour integrated sample. It was during this time frame that the samples inside the building were collected. Sample number 8192-1 was collected under the fresh air intake of the air handling unit (AHU) closest to the corner of Ogden Street and Center Avenue. At the start and at the finish of the collection of this sample, the dampers on the AHU were in a closed position and thus a minimum amount of fresh air was entering through this point. Sample 8192-2 was collected under the fresh air intake of the large AHU in the center of the main building. At the start and at the finish of the sampling, the dampers were partially open, thus some fresh air was entering the building at this point.

The samples collected inside of the building were grab samples. The evacuated canisters had no limiting orifices or flow controllers. The time reported in Table 1 is the time that the valve to the canister was opened. It took between 10 and 15 seconds for the canisters to fill.

The temperature and humidity measurements of the indoor air indicate that the air was being conditioned by the HVAC system. The carbon dioxide levels at three locations inside the building approximated the outdoor levels, indicating an adequate supply of fresh air. The one indoor carbon dioxide level that was elevated was in the first floor storage room, which had limited conditioned air supply.

TABLE 1
Locations and Field Data

Field Sample Number	Lab. Canister Number	Location	Time of Sampling	Temperature (°F) Dry Bulb	Wet Bulb	Humidity (% RH)	Carbon Dioxide (ppm)
8192-1	00063	Roof, underneath AHU nearest the corner of Ogden and Center	Start - 10:40 Finish - 12:41	80 84	74 78	75 76	400
8192-2	00006	Roof, underneath large AHU near center of the building	Start - 10:50 Finish - 12-47	80 84	74 76	75 69	
8192-3	00016	Second Floor - Lunch room	11:03	70	63	68	400
8192-4	00084	Second Floor - Hallway outside of Human Resources	11:10	74	64	58	
8192-5	00147	First Floor - Just outside of elevator	11:23	74	65	61	
8192-6	00024	First Floor - Storage room near pit	11:28	73	63	65	950
8192-7	00158	First Floor - Men's room near vault	11:42	75	68	70	
8192-8	00056	First Floor - Sump pit	11:47	76	69	68	
8192-9	00132	Second Floor - Marketing Office	12:00	73	61	63	325
8192-10	00149	Second Floor - Near elevator	12:09	76	67	62	450

The results are in degrees Fahrenheit (°F), per cent relative humidity (%RH), or parts per million (ppm) as applicable.

Sampling Instructions for Summa Canisters and Flow Controllers

Enclosed you will find evacuated Summa sampling canisters and low volume flow controllers. The black colored valve at the top end of the controller adjusts the flow rate. Please do not change the setting on this valve. The valves have been calibrated precisely for the time period over which you will be sampling. First remove the brass cap at the top of the canister. The flow controller is then attached to the top of the Summa canister. Screw down initially with your fingers, then tighten gently with a 9/16 inch wrench.

The green colored valve on the Summa canister should be turned 1 and 1/4 turns counterclockwise to the open position to begin sampling. Close the green valve at the end of the specified time period. Then remove the flow controller from the canister replace the brass cap and return the flow controllers separately. Please return the canisters to the laboratory for analysis in the boxes in which they were shipped. When returning the flow controllers, please be sure to package carefully to insure that they are not damaged during shipment.

Use the identification labels provided and attach them to the Summa canister handle with the ties provided. PLEASE DO NOT STICK ANY KIND OF TAPE OR LABEL ONTO THE CANISTERS AND DO NOT WRITE ON THE CANISTERS WITH MARKER PENS. Also, do not remove PAI identification label or serial number label. Please complete a chain of custody form and include with the shipment. Thank you.

If you have any questions, please call:

QUOTATION

Submitted to: Arlene Medeiros
ENVIRON
210 Carnegie Center, Suite 201
Princeton, NJ 08540

By: Maria Varallo
Project Manager
Performance Analytical Inc.

Project Reference: Indoor Air (10-12 samples)

SERVICES

Analysis of air samples from Summa Canisters for the 16 Volatile Organic Compounds (VOCs) listed below by Gas Chromatography/Mass Spectrometry (GC/MS) according to EPA Method TO-14.
Price per Sample: $ 275

Target Analytes:

Freon 113
TCE (Trichloroethene)
PCE (Tetrachloroethene)
Benzene
cis-1,2-DCE (cis-1,2-Dichloroethene)
Trans-1,2-DCE (Trans-1,2-Dichloroethene)
1,1-DCA (1,1-Dichloroethane)
Acetone
MEK (Methyl Ethyl Ketone)
Chloroethane
Chloroform
Ethylbenzene
Toluene
Methylene Chloride
1,1,1-TCA (1,1,1-Trichloroethane)
1,1,2,2-TCA(1,1,2,2-Tetrachloroethane)

Rental fee per week (10 days) for precleaned, certified and evacuated six (6) liter stainless steel Summa sampling canisters.
Price per Canister: $ 60 plus shipping

Rental fee per week (10 days) for a precalibrated variable constant differential low volume flow controller.
Price per Controller: $ 25

Thank you for the opportunity to bid on this project.

Date: 7/23/92

Approved by: MTT

This quotation is valid for ninety (90) days.

20954 Osborne Street, Canoga Park, CA 91304 • Phone 818 709-1339 • Fax 818 709-2915

LABORATORY REPORT

Client:	ENVIRON	Date of Report:	08/28/92
Address:	210 Carnegie Center, Suite 201	Date Received:	08/20/92
	Princeton, NJ 08540	PAI Project No:	4502
Contact:	Ms. Arlene Medeiros	Purchase Order:	Verbal

Client Project ID: Compliance Mgt.

Ten (10) Stainless Steel "SUMMA" Polished Canisters labeled:

"8192-1"	"8192-2"	"8192-3"	"8192-4"	"8192-5"
"8192-6"	"8192-7"	"8192-8"	"8192-9"	"8192-10"

The samples were received at the laboratory under chain of custody on August 20, 1992. The samples were received intact. The dates of analysis are indicated on the attached data sheets.

Volatile Organic Compound Analysis

The samples were analyzed by combined gas chromatography/mass spectrometry (GC/MS) for sixteen Volatile Organic Compounds. The analyses were performed according to the methodology outlined in EPA Method TO-14 from the Compendium of Methods for the Determination of Toxic Organic Compounds in Ambient Air, EPA 600/4-84-041, U.S. Environmental Protection Agency, Research Triangle Park, NC, April, 1984 and May, 1988. The analyses were performed by gas chromatography/ mass spectrometry, utilizing a direct cryogenic trapping technique. The analytical system used was comprised of a Finnigan Model 4500 GC/MS/DS interfaced to an Entech 2000 automated whole air inlet system/cryogenic concentrator. A thick film (5 micron) crossbonded 100% Dimethyl polysiloxane megabore column (RT_x-1, Restek Corporation, Bellefonte, PA) was used to achieve chromatographic separation.

The results of analyses are given on the attached data summary sheets.

TABLE OF CONTENTS

I. INTRODUCTION

This Data Usability Summary Report (DUSR) has been prepared following the guidelines provided in New York State Department of Environmental Conservation (NYSDEC) Division of Environmental Remediation *Guidance for the Development of Data Usability Summary Reports*, dated June 1999 and the approved Remedial Investigation Work Plan.

II. ANALYTICAL METHODOLOGIES

The data being evaluated is from the October 5-8, 1999 sampling of 7 groundwaters, 2 soils, 3 air samples and one trip blank. One aqueous matrix spike/matrix spike duplicate/matrix spike blank (MS/MSD/MSB) was collected for volatile organic analysis. One aqueous matrix spike/matrix duplicate (MS/MD) was collected for analysis of metals (total and filtered). Also, one soil matrix spike/matrix duplicate (MS/MD) was collected for the analysis of metals. The analytical laboratory that performed the soil and groundwater analyses is H2M Labs, Inc. located in Melville, New York. Air sample analysis was performed by Air Toxics, LTD located in Folsom, California. A summary of the samples and analyses performed is presented in Table 1.

All of the groundwater samples (plus associated field QC samples) were analyzed for Target Compound List (TCL) volatile organic compounds (VOCs) plus Freon 113 by NYSDEC ASP Method 95-1. All of the soils and two of the groundwater samples were analyzed for 5 metals (barium, copper, lead, silver and zinc) (total and filtered) by NYSDEC ASP CLP-M. The two air samples were analyzed for TCL volatile organics compounds (VOCs) plus Freon 113 by Method TO-14A.

A limited data validation was performed following the general guidelines in United States Environmental Protection Agency (USEPA) Region II, Contract Laboratory Program (CLP) Organics Data Review (CLP/SOW OLM03.1), SOP No. HW-6, Revision #11, June 1996 and Evaluation of Metals Data for the CLP, SOP Revision XI, January 1992. Qualifications applied to the data include "J"/"UJ" (estimated result/quantitation limit), "D" (result reported from a diluted analysis) and "U" (not detected at the reported quantitation limit).

III. DATA DELIVERABLE COMPLETENESS

The laboratory deliverable data package for the air sample analyses was prepared in accordance with Air Toxics, LTD general reporting format, which is equivalent with NYSDEC Category B deliverables. The data packages from H_2M Labs, Inc. for all other sample analyses were prepared in accordance with NYSDEC ASP Category B requirements.

IV. HOLDING TIMES

All analyses were performed within NYSDEC contractual and USEPA Region II technical holding time criteria. It should be noted, however, that the sample cooler containing groundwater samples for metals analysis arrived at the laboratory at 20.0°C. There is no qualifications based upon sample temperature.

V. QUALITY CONTROL DATA

A. QC Blanks

No qualifications were made as a result of blank contamination.

B. Instrument Tune Criteria (Volatile Organics Only)

All NYSDEC ASP instrument tuning criteria were met for the volatile organics analyses.

C. Initial and Continuing Calibrations

The percent difference (%D) for carbon disulfide (50.0%), acetone (88.3%), 2-hexanone (51.5%), 2-butanone (50.2%), 1,2-dichloroethene (total) (29.4%) and tetrachloroethene (28.1%) exceeded the USEPA Region II QC limit of 25%D in one or more of the volatile organic continuing calibrations associated with the aqueous samples. Copies of continuing calibration forms (i.e., Forms 7s) are presented in

Attachment 1. Following USEPA Region II validation guidelines, the results for these compounds were qualified "J"/"UJ" in the associated soil samples. Not all compounds were qualified in all samples. It should be noted that all NYSDEC ASP contractual criteria were met.

All other initial and continuing calibration data for all matrices and fractions were compliant with contractual requirements and USEPA Region II validation criteria.

D. Surrogate/Internal Standard Recoveries (Volatile Organics Only)

All surrogate recoveries were within the QC limits specified in NYSDEC ASP Method 95-1.

E. Matrix Spike/Matrix Spike Duplicate/Matrix Duplicate/Matrix Spike Blank Analyses

The matrix spike percent recoveries for all parameters were within the applicable (i.e., NYSDEC ASP and USEPA Region II) QC limits, and no other qualifications were made.

F. Field Duplicates

No field duplicates were collected during this investigation.

G. Laboratory Control Samples (Metals Only)

The inorganic laboratory control samples (LCSs) were within USEPA Region II and method QC limits, and no qualifications were made to the data.

H. Contract Required Detection Limit Standards (Metals Only)

The Contract Required Detection Limit (CRDL) standards were within USEPA Region II limits, and no qualifications were made to the data.

I. Serial Dilutions (Metals Only)

All ICP serial dilution results were compliant with method and USEPA Region II QC requirements, and no other qualifications were made to the data.

VI. SAMPLE RESULTS

A. Raw Data vs. Reporting Forms

The final results as listed on the reporting forms were in agreement with the raw data, and no transcription/calculation errors were detected.

B. Sample Dilutions

Groundwater samples MW-01, MW-02 and MW-03 required diluted analyses due to elevated levels of target compounds. Results reported from diluted analyses were qualified "D".

C. Quantitation Limits

All quantitation limits were reported in accordance with method requirements, and were adjusted for dilution factors and percent moisture. Several volatile results were qualified "J" by the laboratory indicating an estimate concentration below the quantitation limit. Several metals results were qualified "B" by the laboratory indicating results greater than the instrument detection limit but less than the contract required detection limit.

D. Chromatography (Volatile Organics Only)

No chromatography problems were encountered.

E. Total/Filtered Metals Comparison

The concentration of zinc in the filtered metals analysis of groundwater sample MW-01 was more than 10% higher than the concentration in the total metals analysis of this sample. Following USEPA Region II validation guidelines, the results for zinc were qualified "J" in the total and filtered analyses of sample MW-01.

VII. SUMMARY

All sample analyses were found to be compliant with the method criteria, except where previously noted. Those results qualified "J"/"UJ" (estimated) are considered conditionally usable. URS Greiner Woodward Clyde does not recommend the recollection or reanalysis of any samples at this time.

I. INTRODUCTION

This Data Usability Summary Report (DUSR) has been prepared following the guidelines provided in New York State Department of Environmental Conservation (NYSDEC) Division of Environmental Remediation *Guidance for the Development of Data Usability Summary Reports* (Revised June 1999) and the approved Remedial Investigation Work Plan (September 1999).

II. ANALYTICAL METHODOLOGIES

The data being evaluated is from the July 11-13, 2000 sampling of 6 groundwater samples, one trip blank, and 3 air samples. No site-specific matrix spike/matrix spike duplicate/matrix spike blank (MS/MSD/MSB) samples, field duplicates, or rinse blanks were collected during this sampling event. The analytical laboratory that performed the groundwater analyses is H2M Labs, Inc. located in Melville, New York. Air sample analysis was performed by Air Toxics LTD located in Folsom, California.

The groundwater samples (plus trip blank) were analyzed in accordance with NYSDEC Analytical Services Protocol (ASP), 10/95 Edition, Method 95-1 for Target Compound List (TCL) volatile organic compounds (VOCs) plus freon-113 (i.e., 1,1,2-trichloro-1,2,2-trifluoroethane). The air samples were analyzed in accordance with United States Environmental Protection Agency (USEPA) Method TO-14A for TCL VOCs plus freon-113.

A limited data validation was performed following the general guidelines in USEPA Region II Contract Laboratory Program (CLP) Organics Data Review (CLP/SOW OLM03.1), SOP No. HW-6, Revision #11, June 1996 and Evaluation of Metals Data for the CLP, SOP Revision XI, January 1992. Qualifications applied to the data include "J/UJ" (estimated result/quantitation limit), "D" (result reported from a diluted analysis), "NJ" (presumptive evidence for identification – estimated result), and "U" (not detected at the reported quantitation limit). The data summary forms (Form Is) are presented in Attachment 1.

Documentation. Following USEPA Region II validation guidelines, the results for the compounds associated with the non-compliant standard were qualified as estimated ("J/UJ") in the associated aqueous samples. It should be noted that all NYSDEC ASP contractual criteria were met.

Method TO-14A percent differences (%D) for 2-hexanone (61.3%) and 4-methyl-2-pentanone (70.7%) exceeded the USEPA Region II QC limit of 25%D in the volatile organic continuing calibration associated with air sample SG-07. A copy of continuing calibration form (i.e., Form 7) is presented in Attachment 2 – Support Documentation. Following USEPA Region II validation guidelines, the results for these compounds were qualified as estimated ("UJ") for sample SG-07.

All other initial and continuing calibration data were compliant with contractual requirements and USEPA Region II validation criteria.

D. Surrogate/Internal Standard Recoveries

All surrogate recoveries were within the QC limits specified in NYSDEC ASP Method 95-1. However, Method TO-14A analysis of sample SG-07 exhibited an elevated recovery for 1,2-dichloroethane-d_4. Following USEPA Region II validation guidelines, the detected results were qualified as estimated ("J") for sample SG-07. A copy of surrogate recovery form (i.e., Form 2) is presented in Attachment 2 – Support Documentation.

All internal standard recoveries were within the QC limits specified in NYSDEC ASP Method 95-1 and USEPA Method TO-14A.

E. Matrix Spike/Matrix Spike Duplicate/Matrix Spike Blank Analyses

No MS/MSD/MSB were collected/analyzed during this sampling event.

F. Field Duplicates

No field duplicates were collected/analyzed during this sampling event.

G. Laboratory Control Samples

The laboratory control sample (LCS) results for Method TO-14A were within USEPA Region II and method QC limits. However, the Method 95-1 LCS exhibited a slightly low recovery for freon-113. Since USEPA Region II validation guidelines do not have criteria for LCSs no qualifications were made to the data.

VI. SAMPLE RESULTS

A. Raw Data vs. Reporting Forms

The final results as listed on the reporting forms were in agreement with the raw data, and no transcription/calculation errors were detected.

The chloroform result for sample GZ-06 was revised by deleting the laboratory applied "J" qualifier because the concentration is not below the quantitation limit.

The acetone results for groundwater samples GZ-06, MW-2, and MW-3 were qualified as "NJ", because the sample spectra did not conclusively illustrate it's presence. High levels of freon-113 in the samples made acetone identification difficult. After consultation with H2M, it was determined by the laboratory that acetone is present in these samples. The laboratory based the presence of acetone on the retention time and ion current profile (peak response), rather than the mass spectra.

B. Sample Dilutions

Groundwater samples GZ-01, MW-1, MW-2 and MW-3 required secondary dilution analyses due to elevated levels of one or more of the following target compounds: freon-113, 1,2-dichloroethene (total), and acetone. The results reported from diluted analyses (i.e., qualified "D" by the laboratory) were transcribed to the undiluted Form I and the secondary dilution Form I was crossed out.

Of particular note, methylene chloride was not detected in the undiluted analyses for samples GZ-06, MW-1, and MW-2, but was detected in the secondary dilutions. After consultation with the H2M, the laboratory determined that the presence methylene chloride in the secondary dilutions was attributed to laboratory contamination, and is not actually present in the samples. Therefore, the methylene chloride results from the secondary dilutions were not transcribe to the undiluted Form Is.

C. Quantitation Limits

All quantitation limits were reported in accordance with method requirements, and were adjusted accordingly for dilution factors. Several volatile results were qualified "J" by the laboratory indicating an estimated concentration below the quantitation limit.

D. Chromatography

No chromatography problems were encountered, except for the identification of acetone for samples GZ-06, MW-2, and MW-3, caused by high levels of freon-113, as previously noted.

VII. SUMMARY

All sample analyses were found to be compliant with the method criteria, except where previously noted. Those results qualified "J"/"UJ" (estimated) or "NJ" (presumptive evidence for identification) are considered conditionally usable. URS Corporation does not recommend recollection or reanalysis of any samples at this time.

APPENDIX I

NYSDOH AIR SAMPLE RESULTS

FREON 113 CONCENTRATIONS IN AIR - JULY 11, 2000

Former EMCA Site

Mamaroneck, New York

Results are reported in micrograms per cubic meter ($\mu g/m^3$)

SAMPLE LOCATION	FREON 113 CONCENTRATION
530 Fayette Avenue	
Basement	1.0 [PL] = 0.13 PPBV
First Floor	1.0 [PL]
Outdoor	1.0 [PL]
614 Center Avenue	
Basement	1.0 [PL]
First Floor	1.0 [PL]
Outdoor	1.0 [PL]
Cablevision	
Basement	NA
First Floor	17. = 2.19 PPBV
Outdoor	NS

COMPARISON VALUES	25% - 75% RANGE
US EPA Database[1]	
Indoor	0.0 - 0.0
Outdoor	0.5 - 2.5
NYSDOH Database[2]	
Indoor	<1.0 - <1.0
Outdoor	<1.0 - <1.0

Notes: 1 - The United States Environmental Protection Agency's Volatile Organic Compounds Database (EPA Database) was published in March 1988. This database is a compilation of indoor and outdoor data from studies across the United States.

2 - The New York State Department of Health Database (NYSDOH Database) is a summary of indoor and outdoor air sample results from control homes. The samples were collected and analyzed by the NYSDOH from 1989 through 1996.

< = "less than." The number following a "less than" sign (<) is the lowest level the laboratory test can reliably measure (the detection limit). A "<" before any number means the chemical was NOT detected in that sample.

[PL] = Present, but less than the concentration indicated

NA = Not applicable (i.e., no basement)

NS = Not sampled

Zinc	UG/L	2000	8.4	6.7
Filtered Metals				
Barium	UG/L	1000	NA	97.6
Zinc	UG/L	2000	NA	14.8

NOTES:

Only detected results reported.

( ) - Concentration exceeds Criteria.

* - New York State Department of Environmental Conservation. 1998. Division of Water Technical and Operational Guidance Series (1.1.1), Ambient Water Quality Standards and Guidance Values and Groundwater Effluent Limitations. June, Class GA.

APPENDIX I

NYSDOH AIR SAMPLE RESULTS

FREON 113 CONCENTRATIONS IN AIR - JULY 11, 2000

Former EMCA Site

Mamaroneck, New York

Results are reported in micrograms per cubic meter ($\mu g/m^3$)

SAMPLE LOCATION	FREON 113 CONCENTRATION
530 Fayette Avenue	
Basement	1.0 [PL] = 0.13 PPBV
First Floor	1.0 [PL]
Outdoor	1.0 [PL]
614 Center Avenue	
Basement	1.0 [PL]
First Floor	1.0 [PL]
Outdoor	1.0 [PL]
Cablevision	
Basement	NA
First Floor	17. = 2.19 PPBV
Outdoor	NS

COMPARISON VALUES	25% - 75% RANGE
US EPA Database[1]	
Indoor	0.0 - 0.0
Outdoor	0.5 - 2.5
NYSDOH Database[2]	
Indoor	<1.0 - <1.0
Outdoor	<1.0 - <1.0

Notes: 1 - The United States Environmental Protection Agency's Volatile Organic Compounds Database (EPA Database) was published in March 1988. This database is a compilation of indoor and outdoor data from studies across the United States.

2 - The New York State Department of Health Database (NYSDOH Database) is a summary of indoor and outdoor air sample results from control homes. The samples were collected and analyzed by the NYSDOH from 1989 through 1996.

< = "less than." The number following a "less than" sign (<) is the lowest level the laboratory test can reliably measure (the detection limit). A "<" before any number means the chemical was NOT detected in that sample.

[PL] = Present, but less than the concentration indicated

NA = Not applicable (i.e., no basement)

NS = Not sampled
