Executive Summary

1.0 Introduction & Site History

The Wurlitzer "Area B" site is a wooded 5.5 acre parcel of land which is situated in the south-west corner of the Wurlitzer Industrial Park Complex in North Tonawanda, New York. The Industrial Park, located at 908 Niagara Falls Boulevard, comprises a total area of approximately 44 acres. Figure 1-1 shows the Industrial Park location.

The site is bounded on the north-west side by a former Conrail railroad line. The tracks have been removed and the right-of-way now contains underground Oxbow co-generation power and steam lines. Wurlitzer Drive runs along the western side of the site and intersects with Fairmont Avenue in the residential neighborhood to the north and west of the site. The nearest homes are those along the south side of Fairmont Avenue, near the intersection of Wurlitzer Drive. The back yards of these residences are adjacent to the elevated former conrail line. Figure 1-2 is a map of the Industrial Park and includes details of the Area B.

Area B is wooded, and with the exception of numerous piles of fill, is relatively flat. An abandoned, elevated section of railroad track runs through the south-western corner of the site and ends just before Wurlitzer Drive. This spur once connected with the conrail track at the southern corner of the Wurlitzer plant property. The area of the site along the elevated former Conrail line is relatively low lying and rain water and snow melt accumulates along this side of the site. There also appears to be occasional ponding of water on the south-eastern side of the site.

The Industrial Park was owned and operated by Wurlitzer Industries from 1908 to 1977. The site's facilities were used for the manufacture of several products including automatic phonographs, player pianos, electric organs, and jukeboxes. During its operating history Wurlitzer Industries also utilized this facility for production processes related to several Defense Department contracts. The former Wurlitzer manufacturing building is currently owned by Irr Supply Centers, Inc. and Ancor Industrial Plastics, Inc. The building is currently used for manufacturing and as commercial rental space. Area B consists of tracks of land currently owned by Blue Bird Industrial Park North, Inc. and Ancor Plastics, Inc.

A dirt access road runs through Area B, starting from a gate on the northeast side of the site near the end of the former plant building. It runs parallel to the former Conrail line approximately 2/3 of the way toward Wurlitzer Drive. Aerial photos taken between 1958 and 1966 indicate activity within Area B took place along the southern side of this access road. This activity is believed to have included disposal of various waste materials. Based upon the nature of the manufacturing processes, it is likely that wastes generated at the plant included scrap metal, metal sludges from plating operations, and degreasing wastes.

It appears that the access road was used to deposit various waste material within the confines of Area B. The disposal of fill occurred in the western corner of the site as well as along

either side of the access road along its length, up to and outside the fence gate near the plant. The fill observed on site includes soil, concrete rubble, asphalt rubble, roofing materials, cinders, scrap metal, metal buckets, scrap wood, wooden pallets, and brush. Numerous 55 gallon drum carcasses (crushed or empty) have also been observed throughout the site. In addition, several drums containing solid waste materials were included in the materials deposited on site.

The Wurlitzer Plant property was listed as a suspected hazardous waste disposal site in June 1980. The property consisted of approximately 44 acres and included the former plant buildings, parking lots, and related grounds. In the late 1980s, specific attention was focused on two specific areas of the site, which became known as Area A and Area B. Area A was a parcel of vacant land on the north side of the former Conrail tracks and protruded into the southeastern side of adjacent the residential neighborhood. Area A was believed to have been associated with loading and unloading of materials used in plant production. Area B was a wooded and densely overgrown parcel adjacent to the southwestern portion of the plant.

During the 1990s, a foot path was observed in Area B through the brush along the overgrown former access road. In addition, several indications of site use were noted in 1995. The signs of periodic activity noted by the DEC and DOH during site inspections included: a tree stand (similar to those constructed for hunting purposes), a plywood shelter (i.e. children's play fort), a child's glove, and bottles. In November of 1995, the New York State Department of Health (NYSDOH) recommended that a fence be constructed around Area B to prevent possible direct human contact with any contaminated soils or wastes at the site. In December 1995 one of the Area B site owners installed a temporary orange plastic construction fence (a.k.a. snow fence) around the site.

In March 1996, after concluding that waste and fill materials within Area B posed a significant threat to human health, the NYSDEC reclassified the Wurlitzer site from a Class 2a designation (signifying a temporary classification assigned to a site which has inadequate data for another classification) to a Class 2 designation (signifying a significant threat to the public health or environment - action required) in the New York State Registry of Inactive Hazardous Waste Disposal Sites. In October 1996, to reduce the possibility of direct human contact or incidental ingestion of contaminated waste and fill materials, the NYSDEC funded the installation of a permanent chain link fence around the perimeter of the site.

2.0 Scope of the Remedial Investigation

Beginning in 1989, several limited scope investigations and sampling events have been conducted at the Wurlitzer Area B site. The remedial investigation was performed during 1997 and 1998 to provide a more thorough characterization of existing site conditions, and to obtain the necessary data to determine the nature and extent of any site contaminants.

Non-investigative tasks performed as part of the remedial investigation included: site clearing and grubbing of brush and small trees; disposal of drummed and containerized wastes remaining on site; performance of a site topographic survey; and replacement of a damaged portion

of fence to prevent unrestricted site access.

Investigative tasks performed as part of the remedial investigation included: a geophysical survey to investigate the possibility of buried wastes; collection and analysis of groundwater samples from existing monitoring wells; collection and analysis of basement sump water samples from homes along Fairmont Avenue; collection and analysis of soils samples at 50' x 50' grid intervals throughout the site; and completion of test pits and sampling within fill/waste piles to determine composition of the on site materials.

3.0 Results of the Remedial Investigation

From the data gathered during the remedial investigation, site contamination is limited to the organic and inorganic contaminants in the waste and fill solids which have been disposed of on the site. Both organic and inorganic contaminants were detected in the on-site waste and fill materials significantly above soil guidance criteria contained in NYSDEC Technical and Administrative Guidance Memorandum 4046: Determination of Soil Cleanup Objectives and Cleanup Levels (TAGM 4046). Those organic contaminants of concern detected in the waste and fill material include: benzo[a]anthracene, chrysene, benzo[b]fluoranthene, benzo[k]fluoranthene, benzo[a]pyrene, indeno[1,2,3-cd]pyrene, and dibenz[g,h,i]perylene. Those inorganic contaminants of concern detected in the waste and fill material include: arsenic, barium, cadmium, chromium, lead, and zinc. Tables 3, 4, and 5 list results of the soil sampling from the grid locations and also list NYSDEC TAGM 4046 soil guidance concentrations for each compound.

In an effort to more thoroughly examine the consistency and depth of the various fill piles, 39 test pits were excavated throughout the site. Most fill piles contained black cinder type waste.

Depth to native soils in the non-filled areas of the site is generally between 1 - 3 feet. Test pit excavations indicate that fill materials were disposed only on the surface of the site, and that wastes and fill were not buried below the surface of native soil.

Several samples of material were obtained from the fill areas in these test pits in order to assess fill material characteristics. The results from the test pit samples indicate contaminant concentrations similar to the samples obtained from grid locations taken within fill areas. Samples were taken from 10 of the 39 test pits and analyzed for VOCs, semi-volatiles, and metals. In addition, 3 of the test pit samples were submitted for Toxic Characteristic Leaching Procedure (TCLP) testing (TCLP is a testing procedure design to measure the leachability of contaminants within a waste or soil sample). Figure 5 shows the test pit locations and summarizes significant contaminants detected. Table 6 lists concentrations of the compounds of concern in the samples obtained from the test pits. Table 7 summarizes results of TCLP analysis.

Soil samples taken outside of waste and fill disposal areas do not indicate elevated concentrations of identified site contaminants. Groundwater samples taken from monitoring wells at the site and nearby residential basement sumps indicate that the deposition of fill and waste materials on site has not had a significant effect on the groundwater.

4.0 Environmental Threat Assessment

No formal Habitat Assessment was performed on the Wurlitzer Area B site. Despite some periodic standing water on site, there are no wetlands, streams or other significant surface water features on site. Numerous animal holes and burrows have been observed throughout the site. Squirrels, chipmunks, snakes, and various bird species have been observed on site. Although there is currently a 6 foot high chain link fence surrounding the property, deer have also been observed on the site. These species, especially the burrowing animals, are potentially exposed to the high levels of metals on site through contact with or incidental ingestion of contaminated waste and/or fill. The deer and birds are more wide ranging and not likely to be significantly exposed to contaminants due to the small size of the site.

Clearing of underbrush during the investigation has removed a portion of the existing habitat and has probably displaced some of the wildlife using the site. The extent of future use of the site by wildlife depends upon the re-establishment of this vegetation. However, due to the nature and extent of the contamination detected on site, it is unlikely that the site poses any significant threat to the environment.

5.0 Human Health Exposure Assessment

One potential human exposure pathway- direct contact with and/or incidental ingestion of wastes remaining in drums and containers, was eliminated through the removal and disposal of these remaining materials. This removal action will serve to prevent future acute exposures to known site contaminants.

Since the extent of remaining site contamination is limited to the waste and fill material solids found on the surface of the site, the primary potential human exposure pathways are through direct contact with the waste and fill materials.

Completed pathways which are either known to or may exist include:

- Dermal (skin) contact with contaminated waste and/or fill materials by former or future site users or trespassers;
- Incidental ingestion of contaminated waste and/or fill materials by former or future site users or trespassers.

These potential exposure pathways were addressed in the interim by installing a chain link fence around the perimeter of the site. During the remedial investigation, the fence gate and damaged fence sections near the former Wurlitzer plant building were replaced to provide better site control. Even though the site is currently fenced, these exposure pathways may be still considered "complete", since exposure potential remains for site trespassers and future site users.

6.0 Conclusions

From test pit excavations and hand augering throughout the site, it is apparent that waste, fill materials, refuse, and other debris was disposed of on the surface of the site, and no burial of wastes took place. Groundwater and residential basement sump water sample results indicate that the waste materials disposed at the site have not had a significant effect on groundwater.

Significant organic and inorganic contaminants are present in the waste and fill materials previously disposed on site. While some contaminants are present throughout the site in almost all fill areas, the majority of significant contaminants detected were found in the area of waste and fill material on the southwestern half of the site.

Numerous animals such as squirrels, chipmunks, snakes, birds, deer, etc. have been observed at the site. No formal Habitat Assessment was performed on the Wurlitzer site. However, due to the nature and extent of the contamination present at the site, it is unlikely that the site poses any significant threat to the environment at this time.

Repairs to the fence and replacement of the main gate was completed during the Remedial Investigation. The fence will limit access to the site, but cannot prevent trespassers from gaining access. Despite the fence, potential exposure pathway exist for trespassers or future site workers who may have dermal contact or incidental ingestion of contaminated waste and/or fill materials which remain on site. A Feasibility Study must be performed to evaluate appropriate remedial actions to address these possible exposure pathways.

Section 1: Site Description and History

1.1 Site Description

The Wurlitzer "Area B" site is a wooded 5.5 acre parcel of land which is situated in the south-west corner of the Wurlitzer Industrial Park Complex in North Tonawanda, New York. The Industrial Park, located at 908 Niagara Falls Boulevard, comprises a total area of approximately 44 acres. Figure 1-1 shows the Industrial Park location.

The site is bounded on the north-west side by a former Conrail railroad line. The tracks have been removed and the right-of-way now contains underground Oxbow co-generation power and steam lines. Wurlitzer Drive runs along the western side of the site and intersects with Fairmont Avenue in the residential neighborhood to the north and west of the site. The nearest homes are those along the south side of Fairmont Avenue, near the intersection of Wurlitzer Drive. The back yards of these residences are adjacent to the elevated former conrail line. Figure 1-2 is a map of the Industrial Park and includes details of the Area B.

Area B is wooded, and with the exception of numerous piles of fill, is relatively flat. An abandoned, elevated section of railroad track runs through the south-western corner of the site and ends just before Wurlitzer Drive. This spur once connected with the conrail track at the southern corner of the Wurlitzer plant property. The area of the site along the elevated former Conrail line is relatively low lying and rain water and snow melt accumulates along this side of the site. There also appears to be occasional ponding of water on the south-eastern side of the site.

1.2 Site History

The Industrial Park was owned and operated by Wurlitzer Industries from 1908 to 1977. The site's facilities were used for the manufacture of several products including automatic phonographs, player pianos, electric organs, and jukeboxes. During its operating history Wurlitzer Industries also utilized this facility for production processes related to several Defense Department contracts. The former Wurlitzer manufacturing building is currently owned by Irr Supply Centers, Inc. and Ancor Industrial Plastics, Inc. The building is currently used for manufacturing and as commercial rental space. Area B consists of tracks of land currently owned by Blue Bird Industrial Park North, Inc. and Ancor Plastics, Inc.

A dirt access road runs through Area B, starting from a gate on the northeast side of the site near the end of the former plant building. It runs parallel to the former Conrail line approximately 2/3 of the way toward Wurlitzer Drive. Aerial photos taken between 1958 and 1966 indicate activity within Area B took place along the southern side of this access road. This activity is believed to have included disposal of various waste materials. Based upon the nature of the manufacturing processes, it is likely that wastes generated at the plant included scrap metal, metal sludges from plating operations, and degreasing wastes.

It appears that the access road was used to deposit various waste material within the confines of Area B. The disposal of fill occurred in the western corner of the site as well as along either side of the access road along its length, up to and outside the fence gate near the plant. The fill observed on site includes soil, concrete rubble, asphalt rubble, roofing materials, cinders, scrap metal, metal buckets, scrap wood, wooden pallets, and brush. Numerous 55 gallon drum carcasses (crushed or empty) have also been observed throughout the site. In addition, several drums containing solid waste materials were included in the materials deposited on site.

The Wurlitzer Plant property was listed as a suspected hazardous waste disposal site in June 1980. The property consisted of approximately 44 acres and included the former plant buildings, parking lots, and related grounds. In the late 1980s, specific attention was focused on two specific areas of the site, which became known as Area A and Area B. Area A was a parcel of vacant land on the north side of the former Conrail tracks and protruded into the southeastern side of adjacent the residential neighborhood. Area A was believed to have been associated with loading and unloading of materials used in plant production. Area B was a wooded and densely overgrown parcel adjacent to the southwestern portion of the plant.

During the 1990s, a foot path was observed in Area B through the brush along the overgrown former access road. In addition, several indications of site use were noted in 1995. The signs of periodic activity noted by the DEC and DOH during site inspections included: a tree stand (similar to those constructed for hunting purposes), a plywood shelter (i.e. children's play fort), a child's glove, and bottles. In November of 1995, the New York State Department of Health (NYSDOH) recommended that a fence be constructed around Area B to prevent possible direct human contact with any contaminated soils or wastes at the site. In December 1995 one of the Area B site owners installed a temporary orange plastic construction fence (a.k.a. snow fence) around the site.

In March 1996, after concluding that waste and fill materials within Area B posed a significant threat to human health, the NYSDEC reclassified the Wurlitzer site from a Class 2a designation (signifying a temporary classification assigned to a site which has inadequate data for another classification) to a Class 2 designation (signifying a significant threat to the public health or environment - action required) in the New York State Registry of Inactive Hazardous Waste Disposal Sites. In October 1996, to reduce the possibility of direct human contact or incidental ingestion of contaminated waste and fill materials, the NYSDEC funded the installation of a permanent chain link fence around the perimeter of the site.

1.3 Summary of Previous Investigations

Beginning in 1989, various sections of the Wurlitzer Industrial Park site have been inspected and sampled in order to confirm possible hazardous waste disposal. Significant sampling events and reports generated from this work are summarized in Appendix A and described below.

Phase I Investigation

In 1989 a Phase I Investigation was conducted on the entire Wurlitzer Industrial Park property by Engineering Science and Dames & Moore on behalf of the NYSDEC. The Phase I Investigation consisted of site inspections and background information searches. It did not include any environmental sampling.

Phase II Investigation

In 1990 a Phase II Investigation was conducted on the entire Wurlitzer Industrial Park property by Ecology & Environment on behalf of the NYSDEC. The Phase II Investigation was performed in an attempt to identify hazardous waste disposal at the site and characterize potential impacts from disposal. This investigation included the sampling of surface water, sediment, and waste material piles in selected areas of the plant site. It also included the installation of groundwater monitoring wells and subsequent groundwater sampling. Figure 2 shows the location of the three pairs of monitoring wells installed around Area B as part of the Phase II investigation.

Most of the Phase II sampling was targeted at the two areas of the industrial park property known as Area A and Area B. A figure indicating Phase II sampling locations is contained in Appendix A, Figure A1. Phase II Sampling of Area B included surface soil, sediment from two low lying wet areas, and groundwater. The four surface soil samples taken in Area B indicated the presence of semi-volatile organic contaminants in all of the samples, as well as elevated metals concentrations in one of the samples. The semi-volatile contaminants detected were primarily polycyclic aromatic hydrocarbons (PAHs). The results of this surface soil sampling are summarized in Appendix A, Table A1. Sediment samples from the low lying areas of the site indicated some elevated metals concentrations as well. The results from the sediment sampling are summarized in Appendix A, Table A2. Samples from the groundwater monitoring wells did not indicate the presence of volatile or semi-volatile organic contamination, however several metals were detected in site groundwater above Class GA (drinking water) standards. The results from the groundwater sampling are summarized in Appendix A, Table A3.

1991 Sampling of Wastes

In 1991, the NYSDEC took two samples of waste materials located within Area B. One waste was a "tar"- like substance and the other waste was a sandy solid material which was present in a drum. The "tar" - like sample contained elevated concentrations of volatile organics, PAHs, pesticides, and metals. The sandy material did not contain any significant organic contaminants, but was not tested for metals. These results are summarized in Appendix A, Table A4.

1995 Soils Sampling

In April 1995, the NYSDEC collected 10 surface soil samples from Area B and submitted these samples for metals analysis. Six of the samples were analyzed for total metals and four of the samples were analyzed for leachable metals for toxicity using the Toxicity Characteristic Leaching Procedure (TCLP). Several of the samples contained elevated metals concentrations, however none of the samples submitted for TCLP analysis exhibited an elevated amount of leachable metals. The results of these soil samples are summarized in Appendix A, Table A5. In October 1995, the NYSDEC and NYSDOH took eight soil samples and two waste samples (from drums) within Area B. Several of the soil samples contained elevated metals concentrations. One of the waste samples taken from a drum, a white powder, was tentatively identified as barium sulfate. The sampling results from the other drum cannot be located. The results of these samples are summarized in Appendix A, Tables A6 and A7.

1996 Residential Soil and Surface Water Sampling

In April 1996, the NYSDEC and NYSDOH collected five surface soil samples from residential properties adjacent to Area B. In addition, seven surface water samples were collected from both on-site locations and from the former Conrail line between the residential properties and the site.

The surface water samples did not indicate any significant metals concentrations within the standing waters at and near the site. The results from the surface water samples are summarized in Appendix A, Table A8. The residential soil samples taken in April 1996 indicated elevated concentrations of antimony and thallium. However, the data from the analysis of these soil samples was rejected by the NYSDOH due to quality control problems.

Since previous site sampling had not indicated significant concentrations of these metals, NYSDOH recommended that resampling of the residential soils be performed. In July 1996, the residential soils were resampled. Seven surface soil samples were taken from the same properties adjacent to Area B, and four "background" samples were taken from other residential areas within the community (locations and results of background soil samples are contained in Appendix G). The soil samples taken in July were submitted to the NYSDOH's Wadsworth laboratory (in Albany, New York) for analysis. The results from the resampling of the residential soils did not confirm the previous analysis of the soils performed by the NYSDEC's Saratoga, New York laboratory. Results from both rounds of residential soil sampling are contained in Appendix B. It was concluded that the elevated levels of antimony and thallium were "false-positive" results which were not indicative of the actual concentrations of thallium and antimony in the residential soils.

Section 2: Site Investigation Methodology

2.1 Scope of Field Investigations

The Remedial Investigation was designed to provide a thorough and efficient mechanism for characterizing the nature and extent of contamination within Area B. The scope of work was developed to supplement previous site data and to provide sufficient information to evaluate the need for remedial measures at the site.

The scope of work for the Remedial Investigation included:

- Radiation survey;
- Site clearing and debris removal;
- Disposal of drummed wastes remaining on site;
- Performance of a geophysical survey to investigate the possibility of buried wastes;
- Replacement of the damaged fence and gate on the plant side of the site;
- Completion of a site survey to map topographic features and tie-in sampling locations;
- Collection and analysis of groundwater samples from existing groundwater monitoring wells;
- Collection and analysis of basement sump water samples from several homes along Fairmont Avenue;
- Collection and analysis of surface and subsurface soil samples at 50' X 50' grid intervals throughout the site;
- Completion of test pits within the waste/fill piles to determine the nature of waste deposition; and
- Collection and analysis of samples from waste/fill piles during test pits.

2.2 Description of Field Investigations

Radiation Survey

A radiation survey was performed at the site prior to initial clearing and debris removal activities. The primary reason for the survey was to ensure that no scrap metal or other debris at the site exhibited levels of radiation above background. If scrap metal or debris were found to have radiation levels above background levels, it could complicate the off-site disposal of this material.

Site Clearing and Debris Removal

Various wastes and fill materials have been deposited at the site over the years. Material visible throughout the site and included concrete, scrap metal, rusted drum carcasses, wooden pallets, tires, brush, etc. Deposition generally occurred along the dirt access roadway which had overgrown with vegetation over the years. In addition, small trees and other vegetation has grown through some areas of the fill material. Removal of brush and small trees was necessary to provide access for the investigative tasks. Removal of scrap metal from the surface of the site was necessary in order to complete the geophysical investigation.

Disposal of Remaining Drummed Wastes

Several metal 55-gallon type drums and smaller metal containers with solid waste materials remaining were present on site. It was appropriate to secure the remaining drums and containers in overpack drums, and then sample this material for disposal at a licensed waste disposal facility.

Geophysical Survey

Given the presence of numerous metal drums and drum carcasses throughout the site, it was necessary to investigate the possibility of buried waste materials. An electromagnetic survey was performed to map possible buried metal and changes in soil types.

Fence Repairs

Repair of the fence and replacement of the main gate near the plant was necessary to secure the site and prevent unrestricted access.

Site Survey

A site survey was performed to establish the sampling grid and to map the limits and extent of the waste/fill material deposited at the site. The topographic survey provides information necessary to estimate the volume of waste fill within specific areas of the site.

Groundwater sampling

Previous sampling of the groundwater monitoring wells did not indicate the presence of volatile or semi-volatile organic contaminants. Previous sampling of the wells did indicate minor concentrations of metals in groundwater in excess of State Class GA (drinking water) standards. Due to the known presence of elevated metals in some of the waste solids on site, the monitoring wells were resampled.

Basement Sump Water Sampling

In order to address the possibility of exposures from groundwater contaminant migration, groundwater from the basement sumps of three homes along Fairmont Avenue were sampled.

Surface Soil Sampling

After a 50' x 50' grid was established by the surveyor, soil composite samples were collected from each grid location. Each grid sample was composited from soils collected from a 0-6 inch interval and a 2-3 foot interval. The 0-6 inch interval was chosen to address possible direct human contact with surface soils. The 2-3 foot interval was chosen to provide information to characterize the physical and chemical composition of the fill materials present.

Test Pits and Sampling Within Waste/Fill Piles

Test pits were excavated within the majority of the waste/fill piles to identify the depth, extent, and composition of the materials in the piles. Vertical excavation through the piles continued until native (undisturbed) soils were encountered. Materials from test pits in several waste/fill piles were collected for analysis.

Section 3: Remedial Investigation Results

Several site activities were necessary or appropriate which were not related to site contaminant characterization. These activities included: the clearing of brush, small trees, and debris; proper containment, sampling (for disposal), and off-site disposal of drummed wastes remaining on site; and repair/replacement of a section of the perimeter site fence. Other site activities were necessary to characterize the nature and extent of site contamination. These activities included: a geophysical investigation; a site topographic survey; collection and analysis of groundwater and residential basement sump water samples; and the collection and analysis of soil and fill materials throughout the site. All of these activities are described in greater detail below.

3.1 Radiation Survey

A radiation survey was completed at the site on October 9, 1997 by a qualified employee of Malcolm Pirnie Engineer, Inc. Gamma radiation levels were measured using a Ludlum Model 3 rate meter and Model 44-2 detector provided by Environmental Restoration Group, Inc. of Albuerque, New Mexico.

Levels of background gamma radiation were measured off-site at 0.008 mRems/hour. On site measurements of gamma radiation were measured slightly above background and ranged from 0.010 to 0.015 mRems/hour. The on-site readings indicated that material within the site exhibited normal levels of gamma radiation. The radiation survey results are included in Appendix C. Based upon these results, it was concluded that none of the material present on site posed radiological concerns.

3.2 Site Clearing and Surface Debris Removal

In order to conduct geophysical and land surveying activities, it was necessary to clear the site of the dense underbrush, small trees, scrap metal and other debris. Malcolm Pirnie procured the services of Griffen Industrial Services, Inc. to perform the clearing and grubbing of small trees and brush, as well as debris removal. Griffen subcontracted this site work to Triple S Construction.

A site walkover to discuss the scope of the work was performed on October 24, 1997. Representatives of the NYSDEC, Malcolm Pirnie, Griffen, and Triple S attended the site walkover. A buffer strip of trees and smaller growth (within 50-100 feet of the fence) was marked with surveyor tape along the perimeter of the site near Wurlitzer Drive and the residential backyards. The buffer strip was maintained to ensure some natural visual barrier remained after clearing was performed.

In addition, all significant mature trees on the site (diameter greater than approximately 6 inches) were preserved.

Clearing of the site commenced on October 26, 1997. Cleared brush and small trees were chipped and the chips left on site. Scrap metal and other site debris (numerous tires, wood, railroad ties, concrete, etc) were removed from the site between October 26 - November 4, 1997. A

walkover was performed to inspect this work on November 5, 1997. During this inspection, areas of brush and vines were identified, as well as some scrap metal which had not been removed. The removal and off-site disposal of these materials was completed between November 11- 20, 1997. An additional pile of scrap metal was also removed from the site on December 12, 1997.

3.3 Disposal of Remaining Drummed Wastes

Several drums of waste materials were identified and characterized for disposal purposes. Two drums contained a waste hydroxide salt, two drums contained a barium sulfate waste, two drums contained a tar waste, and one drum contained grease. In addition, some asbestos containing wastes were also containerized in steel drums for disposal purposes.

The wastes were secured in plastic and steel overpack containers on November 25, 1997. These wastes were removed from the site on January 15, 1998 for proper disposal. The non-asbestos wastes were shipped by Environmental Service Group to Chem Met Services in Brownstown Michigan. The asbestos waste was sent by Environmental to Sunstream, Inc. in Binghamton, New York. Appendix D contains copies of the waste manifests for disposal.

3.4 Geophysical Survey

On December 3, 1997, Berkshire Environmental performed a geophysical survey of the site to investigate the possibility of buried wastes at the site. This entailed the use of Electromagnetic (EM) induction to map near-surface electrical conductivity variations. Ground conductivity data is sensitive to buried and surficial metal and changes in subsurface soils, saturation, and dissolved ion concentration.

An EM-31 terrain conductivity system (see Appendix E, figure 1) was used to perform the geophysical survey. This equipment is capable of exploring the subsurface to depths of approximately 15 feet. A 25' x 25' control grid (further dividing the 50' x 50' surveyed grid) was flagged by Malcolm Pirnie and used for the geophysical survey. Berkshire established and labeled an (x,y) coordinate system and located site landmarks relative to the control grid. All EM-31 data were collected and digitally recorded on a 12.5' x 12.5' pattern. A total of 1,685 site points were measured for conductivity. Results of the geophysical survey are contained in Appendix E.

Ground conductivity results reveal high correlation between areas of waste/fill along the access road and the outline of high conductivity readings (see Appendix E, Figures 2, 3, and 4). Ground conductivity readings also indicated elevated background values within the surface mounds. This is indicative of a widespread conductive component within the mounds, such as ash or disseminated metal.

Several discrete anomalies were detected outside the mounded areas. The readings for these anomalies generally are reflective of either single objects or tightly grouped conductive or magnetic objects. The geophysical report recommended physical investigations of these areas. These locations were included as part of the test pit excavation and sampling investigation.

3.5 Site Geology and Hydrogeology

Most of the geologic and hydrogeologic information on the site comes from the Phase II Investigation conducted by Ecology and Environment Engineering. Most of the subsurface characterizations come from either boring logs generated during the installation of the overburden monitoring wells, or from regional geologic and hydrogeologic references.

Geology

Deep soil borings in the overburden were not undertaken as a part of this investigation. However, the Phase II Investigation completed at the site by Ecology and Environment in April 1992 for the NYSDEC did characterize overburden material of Area B. The overburden in this area consists of silt with smaller amounts of sand and clay down to a depth of about 5 feet, where there is a waterbearing lens of fine sand about a foot thick. Below this waterbearing lens, a dry red and gray clay grades downward into a varved clay (thin alternating red and gray layers of clay). Silt seams an inch thick occur throughout these clay units. The clay becomes coarser with depth, and at 31 feet below ground surface grades into a till composed of sandy gravel-clay with shale fragments. Bedrock, the Camillus Shale, was encountered at 36 feet below ground surface.

Hydrology

Two overburden waterbearing zones have been identified at the Wurlitzer site. A shallow overburden waterbearing zone occurs in sand lenses at about 5 feet below ground surface. These shallow lenses are not continuous over the site, so it is not likely that there is significant groundwater presence or movement in this zone. Water levels measured in three shallow monitoring wells in Area B in December 1997 indicate groundwater flow was to the west. Water levels measured in April 1998 indicate flow was to the south. Appendix E contains a summary of groundwater elevation readings and site details indicating general groundwater flow directions. These water levels represent isolated, perched water bearing lenses without significant flow or discharge directions. The water in these lenses is isolated by underlying tight clays from the deep overburden waterbearing zone.

The deep overburden waterbearing zone occurs in the varved (layered) clay from about 14 feet below ground surface to the top of rock at about 36 feet below ground surface in Area B. Water levels in three monitoring wells installed in this zone measured in December 1997 and April 1998 indicate flow is generally to the northwest (see Appendix F). Hydraulic conductivity measurements were not made, however, due to the tight nature of the clay, it is likely that groundwater flow in the deep overburden waterbearing zone is not significant.

3.6 Groundwater Sampling

As part of the remedial investigation, three pairs of groundwater monitoring wells

previously installed in the Phase II Investigation (installed and last sampled in 1989/90) were selected for sampling (see Figure 2). Each well pair consists of a shallow and a deeper overburden well. The shallow wells are generally screened approximately 5-7 feet below ground surface, and the deeper wells are generally screened approximately 25-35 feet below ground surface.

Groundwater sampling was performed during December 8, 1997. Samples were analyzed for VOCs, SVOCs, and metals. With the exception of acetone (detected at 7.8 parts per billion in one well), no VOCs or SVOCs were detected in site groundwater above Class GA (drinking water) standards. The detection of acetone in this low of a concentration is most likely a laboratory induced contaminant (glassware cleaning is frequently responsible) and not truly reflective of groundwater characteristics.

Some metals were detected in concentrations above Class GA standards in the groundwater samples. These included one exceedence of chromium in well MW-5S (61.5 ppb vs. Class GA standard of 50 ppb), one exceedence of iron in well MW-6 (3010 ppb vs. Class GA standard of 300), and exceedences of sodium in each of the wells. However, metals concentrations which exceed Class GA standards are not uncommon in groundwater samples. Since the samples are not filtered, the concentrations are often caused by the presence of fine silts or other suspended media in the sample. In this case, the concentrations of metals detected in the samples do not indicate any significant groundwater contamination at the site. In addition, direct human consumption of the groundwater near the site is unlikely since the residential neighborhood does not use groundwater for drinking water purposes. Drinking water is supplied to the homes through the City's public water supply system.

3.7 Basement Sump Water Sampling

Three homes along Fairmont Avenue were selected for basement sump water sampling. These three homes were selected based upon proximity to the site, location along Fairmont Avenue, and homeowner availability and willingness to participate in basement sump sampling.

On December 8-9, 1997 NYSDEC and NYSDOH representatives visited numerous homes along Fairmont Avenue to select and schedule sampling at three residential basement sumps. On December 10, 1997, the same State representatives sampled groundwater from three residential basement sumps. All three residents interviewed indicated that basement sump pumps were in frequent operation and at least one resident indicated that their sump pump operated on a near continuous basis.

Basement sump water from the residences were sampled for VOCs, SVOCs, and metals. With the exception of acetone, which was detected in extremely low concentrations (and is most likely a laboratory contaminant), no VOCs or SVOCs were detected. With regard to metals results, only magnesium and sodium were detected above NYS Class GA water standards. Results of these sump water samples are listed in Table 2.

3.8 Soil Sample Results From Grid Locations

On December 8 - 12, 1997 soil samples were collected from each 50' x 50' grid location staked during the site survey. This corresponded to the collection of approximately 113 soil samples. One composite sample from each location was obtained using a hand auger. The sample was composited from material taken from a 0-6 inch depth and a 2-3 foot depth at each location. Samples were composited within a stainless steel mixing bowl which was decontaminated between locations. Each sample was submitted to the laboratory for SVOC and metals analysis. Several samples were also submitted for VOC analysis.

Soil concentrations at the site were compared to the concentrations listed in the NYSDEC Technical and Administrative Guidance Memorandum 4046: Determination of Soil Cleanup Objectives and Cleanup Levels (TAGM 4046). For evaluation of metals concentrations, soils samples were also compared to metals concentrations detected in background soil samples taken by the NYSDOH at several locations in the community in 1996 (as part of the residential soil sampling program performed). The four background soil samples were collected at: a baseball field in Leah Park; St. Matthews Cemetery; the West Canal Marina; and the Wurlitzer Pool near the swings. These locations are shown in Appendix G, figure G1. The results of the background samples, and average concentrations for the background samples are contained in Table G1 of Appendix G.

Metals

The following metals were detected above NYSDEC TAGM 4046 soil guidance levels in at least one of the boring samples: aluminum, arsenic, barium, beryllium, cadmium, calcium, chromium, copper, iron, lead, magnesium, manganese, mercury, nickel, selenium, silver, sodium, zinc, and cyanide. Of the metals detected above NYSDEC TAGM 4046 levels, arsenic, barium, cadmium, chromium, lead, and zinc are considered to be compounds of concern for the site. Calcium, copper, iron, manganese, nickel and sodium were detected in several site soil samples above NYSDEC TAGM 4046 levels, but were not present in concentrations which would indicate that they are compounds of concern for the site. Table 3 lists results of the soil sampling from the grid locations and lists NYSDEC TAGM 4046 concentrations for each inorganic compound.

The results of the soil sampling from the grid locations indicate a high correlation between samples with elevated levels of metals and the waste/fill pile locations. Figure 3 shows the areas of the site with elevated metals concentrations. One general area of fill accounted for the majority of the exceedences of NYSDEC TAGM 4046 soil guidance levels for metals of concern. This area of fill is located on the southwest portion of the site (the half of the site closer to Wurlitzer Drive) and is located throughout grid locations CS 150-500, CS 150-550, CS 150-600, CS 200-500, CS 200-550, CS 200-600, CS 250-600, CS 300-650, CS 350-650, CS 350-550, CS 400-600, and CS 400-650. This area exhibited the highest concentrations of arsenic, barium, cadmium, chromium, lead, and zinc. The concentrations of metals of concern in this area are significantly above

NYSDEC TAGM 4046 soil guidance levels, and are also well above background levels. It should be noted that this general area of fill material corresponds to the location of a multi colored granular waste material, as well as the area where several of the drummed wastes were found.

Several of the fill piles located along the dirt access road (which runs from the fence gate on the plant side of the site toward the larger area of fill near Wurlitzer Drive) also contained metals concentrations which exceeded NYSDEC TAGM 4046 guidance levels.

Semi-Volatile Organics

Several Semi-Volatile Organic Compounds (SVOCs) were detected at the site in concentrations which exceed NYSDEC TAGM 4046 soil guidance levels. Most of the SVOCs detected are Polyaromatic Hydrocarbon compounds (PAHs) associated with oil and grease, combustion byproducts, and asphalt products. Table 4 summarizes semi-volatile concentrations for soil samples taken at each grid location, and lists NYSDEC TAGM 4046 soil guidance levels for each compound. In nearly all instances, the areas of the site with the highest PAH concentrations were also areas with elevated metals concentrations. These locations included CS 200-650, CS 250-350, Cs 300-100, CS 300-250, CS 300-450, Cs 350-200. PAHs detected in the highest concentrations included benzo[a]anthracene, chrysene, benzo[b]fluoranthene, benzo[k]fluoranthene, benzo[a]pyrene, indeno[1,2,3-cd]pyrene, and dibenz[g,h,i]perylene. Figure 4 shows the areas where elevated PAHs were detected.

Volatile Organics

Several of the soil samples obtained from the grid locations were analyzed for volatile organic compounds (VOCs). The soil samples selected for VOC analysis were those in or near areas of fill/waste which were characterized by discolorations or proximity to former drum locations. Several VOC compounds were detected, but none were detected in significant concentrations. The results of the VOC sampling in grid location soils are summarized in Table 5.

3.9 Soil Sample Results From Test Pit Excavation Locations

In an effort to more thoroughly examine the consistency and depth of the various fill piles, 39 test pits were excavated throughout the site. Test pit log descriptions are contained in Appendix H. Most fill piles contained black cinder type waste. Depth to native soils in non-fill areas of the site generally range between 1 - 3 feet. From test pit excavations it is evident that fill materials were disposed only on the surface of the site, and that wastes and fill were not buried below the surface of native soil.

Several samples were obtained from the fill areas in order to assess the fill material characteristics. The results from the test pit samples indicate similar contaminant concentrations as the samples obtained from grid location samples which were taken within fill areas. Figure 5

shows test pit locations. Samples were taken from 10 of the 39 test pits and analyzed for VOCs, semi-volatiles, and metals. In addition, 3 of the test pit samples were submitted for Toxic Characteristic Leaching Procedure (TCLP) testing. TCLP is a testing procedure design to measure the leachability of contaminants within a waste or soil sample. TCLP results indicate leachable concentrations of cadmium in excess of regulatory levels in 2 of the 3 samples. No other organic or inorganic TCLP exceedences were detected. Table 6 lists concentrations of compounds of concern in the samples obtained from the test pits, and Table 7 summarizes results of TCLP analysis.

3.10 Human Health Exposure Assessment

Using information gathered from the remedial investigation, a qualitative human health exposure assessment was performed for the site. A qualitative exposure assessment considers the type of contaminants found on site, the contaminant concentrations, the extent of the site media effected, and the potential for exposure pathways which could result in human exposure to the contaminants.

Nature and Extent of Site Contamination

Based upon data gathered during the remedial investigation, it appears that site contamination is limited to the organic and inorganic contaminants within in the waste and fill solids which have been disposed of on the site. Both organic and inorganic contaminants were detected in the on-site waste and fill materials significantly above NYSDEC TAGM 4046 soil guidance. Those organic contaminants of concern detected in the waste and fill material include: benzo[a]anthracene, chrysene, benzo[b]fluoranthene, benzo[k]fluoranthene, benzo[a]pyrene, indeno[1,2,3-cd]pyrene, and dibenz[g,h,i]perylene. Those inorganic contaminants of concern detected in the waste and fill material include: arsenic, barium, cadmium, chromium, lead, and zinc. Soil samples taken outside of waste and fill disposal areas do not indicate elevated concentrations of site contaminants.

Site groundwater was sampled during the 1990-1991 Phase II investigation as well as during the Remedial Investigation. Iron, magnesium, manganese, and chromium were detected in at least one of the groundwater samples above NYSDEC Class GA (drinking water) standards. Of these compounds, only chromium is considered a site contaminant which may be related to waste/fill disposal on site. Since the groundwater samples were taken unfiltered (using paper or other filtration to remove fine suspended materials), concentrations of iron, magnesium, manganese, and other metals in excess of NYSDEC Class GA standards are not uncommon. Chromium was detected in two of the groundwater samples in concentrations slightly in excess of Class GA standards (i.e. 61 ppb vs. Class GA standard of 50 ppb).

As an additional assessment of groundwater quality in the vicinity of the site, several residential basement sumps were sampled from homes along Fairmont Avenue. Both magnesium

and sodium were detected in basement sump water samples in excess of NYSDEC Class GA standards, however none of the contaminants of concern for the site were detected in basement sump waters.

Potential Human Health Exposure Pathways

The five elements of an exposure pathway are 1) the source of the contamination; 2) the environmental media and transport mechanism; 3) the point of exposure; 4) the route of exposure; and 5) the receptor population. These elements of an exposure pathway may also be based upon past, present, or future events. Since the extent of site contamination is limited to the waste and fill material solids found at the site, the primary potential human exposure pathways are through direct contact with the waste and fill materials.

Completed pathways which are either known to or may exist include:

- Dermal (skin) contact with contaminated waste and/or fill materials by former or future site users or trespassers;
- Incidental ingestion of contaminated waste and/or fill materials by former or future site users or trespassers.

These potential exposure pathways were addressed in the interim through the installation of a chain link fence around the perimeter of the site. During the remedial investigation, the fence gate and damaged fence sections near the former Wurlitzer plant building were replaced to provide further site control. However, while the site is currently fenced, the above exposure pathways may be still considered "complete" since exposure potential remains for site trespassers and future site users.

3.11 Environmental Threat Assessment

The Wurlitzer Area B site lies between residential and commercial/industrial areas. It is approximately 5 acres in size and contains mixed hardwood trees which vary in diameter from several inches to several feet. Prior to site investigations, most of the site was overgrown with thick brush, including brush and weed growth throughout much of the waste and fill areas of the site. Two low-lying areas of the site exist which area relatively free of fill materials. These areas are the northwestern side of the site adjacent to the property fence, and the southern side of the site adjacent to the elevated railroad spur. These low-lying areas frequently contain standing water from precipitation and snowmelt.

The site's underbrush was cleared and removed from the site in order to perform the investigation. In addition, several small trees (generally less than 6 inches in diameter) were cut and chipped on site to facilitate investigation activities. Existing trees and brush were not removed

along the property boundaries nearest Wurlitzer Drive and the backyards of the homes along Fairmont Avenue. This growth was preserved to provide a "buffer strip" (primarily a visual barrier) between the site and the surrounding property.

No formal Habitat Assessment was performed on the Wurlitzer Area B site. Despite some periodic standing water on site, there are no wetlands, streams or other significant surface water features on site. However, numerous animal holes and burrows have been observed throughout the site. Squirrels, chipmunks, and various bird species have been observed on site. Although there is currently a 6 foot high chain link fence surrounding the property, deer have also been observed on the site. These species, especially the burrowing animals, are potentially exposed to the high levels of metals on site through contact with or incidental ingestion of contaminated waste and/or fill. The deer and birds are more wide ranging and not likely to be significantly exposed to contaminants due to the small size of the site.

Clearing of underbrush during the investigation has removed a portion of the existing habitat and has probably displaced some of the wildlife using the site. The extent of future use of the site by wildlife depends upon the re-establishment of this vegetation. Due to the nature and extent of the contamination detected on site however, it is unlikely that the site poses any significant threat to the environment.

Section 4: Conclusions

From test pit excavations and hand augering throughout the site, it is apparent that waste, fill materials, refuse, and other debris was disposed of on the surface of the site, and no burial of wastes took place. Groundwater and residential basement sump water sample results indicate that the waste materials disposed at the site have not had a significant effect on groundwater.

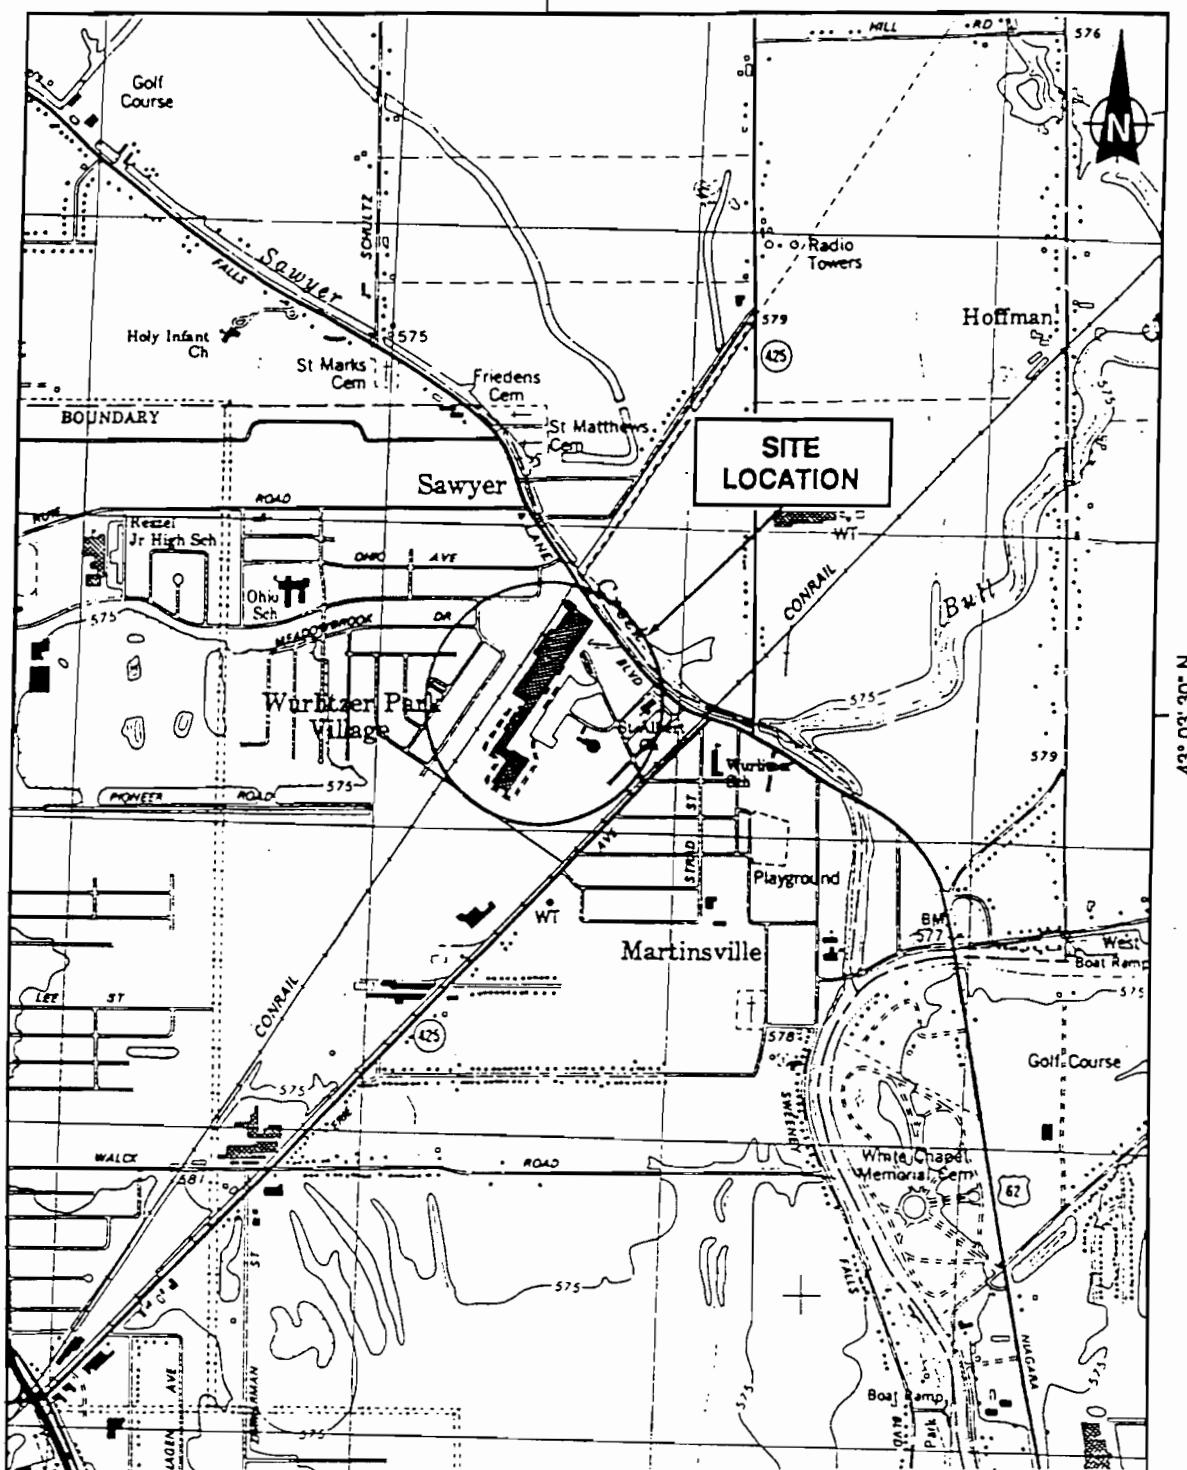

Significant organic and inorganic contaminants are present in the waste and fill materials previously disposed on site. While some contaminants are present throughout the site in almost all fill areas, the majority of significant contaminants detected were found in the area of waste and fill material on the southwestern half of the site.

Numerous animals such as squirrels, chipmunks, snakes, birds, deer, etc. have been observed at the site. No formal Habitat Assessment was performed on the Wurlitzer site. However, due to the nature and extent of the contamination present at the site, it is unlikely that the site poses any significant threat to the environment at this time.

Repairs to the fence and replacement of the main gate was completed during the Remedial Investigation. The fence will limit access to the site, but cannot prevent trespassers from gaining access. Despite the fence, potential exposure pathway exist for trespassers or future site workers who may have dermal contact or incidental ingestion of contaminated waste and/or fill materials which remain on site. A Feasibility Study must be performed to evaluate appropriate remedial actions to address these possible exposure pathways.

Notes:

Only those compounds detected in at least one sample have been included in this table.
 SB = Soil background. Numbers in () indicate average of 4 background sample concentrations.

NA = Not available.

ND = Compound was analyzed for, but not detected.

B = Inorganic concentration is above the instrument detection limit but below the contract required detection limit.

E = Concentration is estimated because of the presence of interference.

NE= Compound was not included in the analysis

VOLATILE ORGANIC COMPOUNDS							
Acetone	200	NA	NA	NA	NA	33	NA
4-Methyl-2-Pentanone	1,000	NA	NA	NA	NA	6.5	NA
Xylenes(total)	1,200	NA	NA	NA	NA	ND	NA

Notes:

Only those compounds detected in at least one sample have been included in this table.

- * The volatile organic compound results are from sample TP-14RE
 - (2) Background levels for lead vary widely. Average levels in undeveloped, rural areas may range from 4-61 ppm. Average background levels in metropolitan or suburban areas or near highways are much higher and typically range from 200-500 ppm.
 - (3) Some forms of cyanide are complex and very stable while other forms are pH dependent and hence are very unstable. Site specific form(s) of cyanide should be taken into consideration when establishing soil cleanup objectives.
 - (4) As per TAGM #4046, Total VOCs, 10 ppm, Total Semi-VOCs , 500 ppm, and individual Semi-VOCs, 50 ppm.
- NV = No Value.
- MDL = Method Detection Limit.
- NA = Not Analyzed.
- ND = Compound was analyzed for, but not detected.
- D = Value was taken from a diluted test sample
- J = Concentration has been estimated.
- B = Inorganic concentration is above the instrument detection limit but below the contract required detection limit.
- NE= compound was not included in the analysis

Appendix A

Table A1
Wurlitzer Site (#9-32-041) - Past Investigations/Sampling

<u>Date</u>	<u>Event</u>	<u>Results</u>
Jan. 1989	E&E Phase I Invest.	Recommended no further action despite possible on-site disposal of wastes
Apr. 1992	E&E Phase II Invest.	Aerial photos indicate on-site disposal in areas "A" and "B"; documentation of on-site disposal of TCE still bottoms (location of disposal unknown); metals detected in groundwater above class "GA" stand; waste sampled in area B contained PAHs, VOCs, and pesticides.
1991	Region 9 sampling	Samples taken of tar/waste and solids in drums in area "B". Tar waste contains Dichlorobenzenes at up to 160 ppm; other PAHs.
Oct. 1995	DEC/DOH sampling of Area B.	Six (6) samples taken: 2 samples taken from drums - one white solid and one tar like waste - these substances were tentatively identified as Barium Sulfate (used in production of artificial ivory - i.e. piano keys) and partially evaporated fuel oil; 4 soil samples taken near solvent tanks and discharge pipes - contained arsenic, lead, cadmium, chromium, and nickle above health-based soil criteria.
Apr. 1996	DEC/DOH sampling of residential surface soil from backyards adjacent to Area B.	Five (5) backyard surface soil samples and several surface water samples from on-site in Area B. Backyard soil samples show elevated antimony and thallium concentrations (although these metals have not been found in similar concentrations on-site). DOH recommended resampling to confirm concentrations.
July 1996	DEC/DOH re-sampling of residential surface soils	Seven (7) backyards were sampled along with 4 "background" samples taken from other neighborhoods. Elevated levels of antimony and thallium previously detected by DEC labs were not confirmed.

TABLE A1

**NEW YORK STATE DEPT. OF ENVIRONMENTAL CONSERVATION
WURLITZER AREA B SITE REMEDIAL INVESTIGATION WORK PLAN**

SUMMARY OF HISTORICAL SURFACE SOIL ANALYTICAL RESULTS (E&E, 1990)

Parameter ⁽¹⁾	TAGM 4046 Guidance	S-5	S-6	S-7	S-8
Volatiles ($\mu\text{g}/\text{kg}$): Trichloroethylene	700	ND	ND	7	ND
Semi-Volatiles ($\mu\text{g}/\text{kg}$): Total PAHs ⁽²⁾	500,000	920	1,800	26,000	13,000
Pesticides ($\mu\text{g}/\text{kg}$): Endosulfan Sulfate	1,000	ND	ND	ND	190
PCBs ($\mu\text{g}/\text{kg}$): Aroclor-1254	1,000	ND	ND	ND	750
Inorganics (mg/kg):					
Barium	300	ND	ND	ND	6,900
Cadmium	10	2.0	47.7	ND	74.8
Copper	25	ND	ND	ND	1,360
Lead	30	ND	464	ND	1,280
Silver	200	ND	9.3	ND	6.8
Zinc	20	ND	ND	ND	3,050
Cyanide	N/A	ND	ND	ND	130
Notes:					
(1) Only those parameters detected above the PQL in at least one sample are listed.					
(2) Since PAHs were detected in all samples, compounds detected below the CRQL were included in the total. Therefore, these values are considered estimates.					
ND = Compound not detected above the PQL.					
N/A = Cleanup goal not available.					
Shading indicates concentrations above TAGM 4046 Soil Guidance.

Vanadium	150	83.7	ND	21.4	19.67	15.5	20.9
Zinc	20	625	1,050	28.1	ND	36.9	56.8

Notes:

SB = Soil background

ND = Compound not detected above PQL

NB - Compound not detected above TQE.
Shading indicates concentration above TAGM 4046 soil guidance

S 1: Red brick-like material

S-1: Red brick-like material.
S-2: Bits of mortar-like chunks

S-2. File of mortar-like chunks.
S-3, S-4, S-5, S-6, S-7, S-9; Black ash-like material

S-3, S-4, S-5, S-6, S-7, S-9. Black
S-8. Wet soil from middle of path.

S-10: Waste from collapsed dump

S-10: Waste from collapsed drum.

Samples S-3, S-5, S-9, and S-10 were analyzed as TCLP extract samples and no compounds were detected.

TABLE A7 (continued)

NEW YORK STATE DEPT. OF ENVIRONMENTAL CONSERVATION
WURLITZER AREA B SITE REMEDIAL INVESTIGATION WORK PLAN

SUMMARY OF HISTORICAL SOIL ANALYTICAL DATA (10/12/95)

Notes:

ND= Compound not detected above PQL.

SB = Site background.

N/A = Cleanup goal not available.

Shading indicates concentrations above TAGM cleanup goals.

W1: Fill material with white chalky veins.

W2: Variable fill texture and color.

W3: Waste material sample from mound.

W4: Stained soil around corroded drum.

H1: Brown surface soil.

H3: Green clay surface soil.

H4: Green clay surface soil.

H5: Yellow/white surface soil.

Sample H2 was collected from drum waste and is presented separately in Table A6.

TABLE A8

**NEW YORK STATE DEPT. OF ENVIRONMENTAL CONSERVATION
WURLITZER AREA B SITE REMEDIAL INVESTIGATION WORK PLAN**

SUMMARY OF HISTORICAL SURFACE WATER ANALYTICAL DATA (4/96)

Inorganic ⁽¹⁾ ($\mu\text{g/L}$)	Class C Water Qual. Standard	SW-1	SW-2	SW-3	SW-4	SW-5	SW-6	SW-7
Aluminum	100	520	70	260	100	160	170	150

Chromium	⁽²⁾	330	60	70	30	30	30	40
Copper	⁽²⁾	310	190	240	130	100	80	80
Iron	300	2,000	120	500	90	120	1,600	370
Lead	⁽²⁾	100	50	50	30	40	50	60
Magnesium	N/A	500,000B	500,000B	500,000B	500,000B	139,000B	450,000B	500,000B
Manganese	N/A	430	50	70	30	30	70	70
Nickel	⁽²⁾	ND	ND	420	20	30	30	40
Potassium	N/A	15,000	9,500	8,900	11,000	700	3,000	5,200
Selenium	1	90	100	80	80	80	100	110
Sodium	N/A	9,000	4,500	10,900	1,900	1,870	2,400	7,200
Thallium	8	180	210	160	150	180	170	210
Zinc	30	30	ND	ND	ND	ND	ND	ND

Notes:

⁽¹⁾ Only those inorganic compounds that were detected in at least one sample are presented.

⁽²⁾ Depends on hardness

⁽³⁾ Guidance Value.

N/A = Water quality standard or guidance value for Class C is not available.

ND = Compound not detected above practical quantitation limit (PQL).

J = Indicates an estimated value below PQL.

B = Also found in associated blank.

Shading indicates concentrations above NYSDEC Class C Water Quality Standards.

RADIATION SURVEY

0266-33-2100

Site Information

Name/Location: Wurlitzer Area B Site, North Tonawanda, New York

Date of Survey: 10/09/97 Weather: clear 70°

MPI Employee Conducting Survey: Ken Kota

Current TLD Badge: Yes Date on Badge: 10/01/97

Radiation Meter

Manufacturer: Ludlum Measurements, Inc., Sweetwater, TX (915) 235-5494

Distributer: Environmental Restoration Group, Inc., Albuquerque, NM (505) 298-4224

Model: 3 (rate meter); 44-2 (detector)

Calibration Date: 4/7/97 Calibration Due Date: 4/7/98

Radiation Measured: Gamma

Meter Readings

Background: 8 $\mu\text{R}/\text{hr}$ X (0.001 mR/ μR) = 0.008 mR/hr

(Note: typical background ~ 20 $\mu\text{R}/\text{hr}$ = 0.02 mR/hr)

Permissible Detection Range:

2X Background: 16 $\mu\text{R}/\text{hr}$ X (0.001 mR/ μR) = 0.016 mR/hr

Upper Limit: 500 $\mu\text{R}/\text{hr}$ X (0.001 mR/ μR) = 0.5 mR/hr

RADIATION SURVEY

Location Description	Reading	
	$\mu\text{R}/\text{hr}$	mR/hr
along trail from West to East fences	15	0.015
north of trail amongst piles of debris	10-15	0.01-0.015
south " " " " "	10-15	0.01-0.015
southern half of site to new fence line	10-12	0.01-0.012

- majority of debris piles are on either side of the east/west trail.
- entire site is covered with dense brush with scattered trees, 6"-12" Ø.
- marsh area located in approx. center of southern section.

On behalf of the generator, I certify that all information contained in this profile, including any attachments is complete, factual and accurate. It represents the known and suspected hazards and waste generator regulations pertaining to the waste described above.

I am a duly authorized representative of the generator. Generator agrees to indemnify and hold the Environmental Service Group (NY), Inc. (ESG) harmless for any claims, liabilities, damages and costs arising out of or in any way related to breach of the above certification. I further authorize ESG to transmit the above information to regulatory or TSD facilities as required for disposal.

Subject: *Results of a Geophysical Investigation, North Tonawanda, New York*

Dear Ms. Secker,

Berkshire Environmental, Inc. (Berkshire) performed an electromagnetic (Geonics EM-31) survey at the Wurlitzer Site, North Tonawanda, New York on Wednesday, December 3, 1997. Surface conditions at the site were characterized by random surface debris as well as large diameter (~15 ft) and irregular-shaped mounded piles. The purpose of the investigation was to detect possible buried drums within the ~5 acre survey area.

Results of the investigation reveal an extensive 'T'-shaped area of high-amplitude ground conductivity values oriented northeast-southwest. Some surface scrap and piles of debris are included within this region, however conductive boundaries are defined more by mounding than surface features. Elevated background values dominate the ground conductivity map which suggests a conductive component to the soil. Numerous bulls-eye anomalies that are not related to noted surface features were also interpreted on both in-phase and ground conductivity maps. Berkshire recommends physical inspection of these areas.

1.0 ELECTROMAGNETIC THEORY & INSTRUMENTATION

Electromagnetic (EM) induction is a non-invasive geophysical technique implemented to map near-surface electrical conductivity variations. The EM method involves the generation of an alternating magnetic field which causes eddy currents to flow in conductive materials. These eddy currents produce a secondary magnetic field which is sensed and measured by the field instrumentation. The apparent electrical conductivity of the subsurface is derived by comparing the primary magnetic field with the measured secondary field and recorded in millSiemens/meter (mS/m), the inverse of resistivity. Ground conductivity data are sensitive to buried and surficial metal and changes in subsurface soils, saturation, and dissolved ion concentration. In-phase values, a second mode of data, are sensitive to both ferrous and non-ferrous metal and are recorded in parts per thousand (ppt).

EM exploration depth is dependant on the spacing between the transmitter and receiver coils and their orientation. For this study, Berkshire utilized its in-house Geonics EM-31 terrain conductivity system with an intercoil spacing of 12 ft. Ground conductivity and in-phase data were digitally recorded at each station in the vertical dipole mode to explore subsurface depths to approximately 15 ft (Figure 1).

2.0 FIELD DESIGN

A 25 x 25 ft control grid was flagged and cleared of vegetation by **Malcolm Pirnie, Inc.** prior to Berkshire mobilization. Berkshire established and labeled an (x,y) coordinate system and located site landmarks (fence, railroad tracks) relative to the control grid (Figure 2). All EM-31 data were collected and digitally recorded on a 12.5 x 12.5 ft pattern in accessible areas. In total, 3,370 data values (1,685 points) were recorded.

All EM-31 data were digitally stored, downloaded to a computer and reviewed for data QA/QC in the field. Berkshire generated preliminary contour maps of the ground conductivity and in-phase data and relayed preliminary interpretations to the **Malcolm Pirnie, Inc.** representative. Although numerous anomalies were identified, a distinction between the effects of known surface features vs. unknown buried targets were not determined in the field. As a result, only one interpreted EM-31 anomaly was field flagged.

3.0 DATA INTERPRETATION

Final data plots were splined and contoured using SURFER v.6.01 software package. The resolution of all interpreted EM-31 anomalies is constrained by the 12.5 x 12.5 ft data collection spacing and interpolation between adjacent data points.

The ground conductivity interpretation map (Figure 3) is dominated by a cluster of high-amplitude anomalies within a northeast-southwest trending "T"-shaped area. Some surface scrap and debris piles are included within this region, however this area is not defined by surface features alone. A correlation also exists between observed surface mounding and area boundaries. Isolated "bulls-eye" anomalies are also present which do not appear to be related to noted surface features. Four additional bulls-eye responses are located outside the "T" zone, centered at coordinates (325,675), (387.5,525), (37.5,362.5), and (362.5,150).

Based on their limited lateral extent, these bulls-eye responses are interpreted as either single metallic targets or tightly grouped objects. The ground conductivity map is also characterized by elevated background values (40-50 mS/m). This suggests a conductive component is present in the soil, such as disseminated metal or ash.

Although the "T" area is relatively apparent on the in-phase component as well, the most prominent features observed on this map (Figure 4) are the numerous bulls-eye anomalies. Highlighted in yellow, they can be found at coordinates (162.5,587.5), (212.5,112.5), (362.5,125), (362.5,212.5), (37.5,362.5), (387.5,525), (412.5,587.5), (362.5,550), (237.5,612.5), and (325,675). Several anomalies overlap or are adjacent to surface debris, however their extent beyond debris limits suggests additional buried targets may exist in these areas. Berkshire recommends physical investigations of all EM-31 anomalies to determine their source. Berkshire also recommends close examination of noted surface features to verify that they are in fact the source of high-amplitude values recorded in their vicinity.

4.0 CONCLUSIONS & RECOMMENDATIONS

On December 3, 1997 Berkshire performed an EM-31 survey at the Wurlitzer Site in North Tonawanda, New York to detect possible buried drums within an ~5 acre survey area. In total, 1,685 EM-31 grid locations were surveyed and digitally recorded on a 12.5 x 12.5 ft grid pattern.

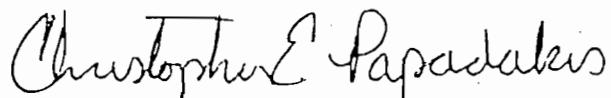

The most prominent feature on site is the "T"-shaped area of high-amplitude values. This zone is interpreted to be the result of surface debris combined with buried metallic and conductive targets. Elevated background values observed on the ground conductivity map suggest a conductive soil component is also present within the mounds.

Numerous bulls-eye anomalies were interpreted on both the ground conductivity and in-phase maps. Bulls-eye responses are typically recorded over either single targets or tightly grouped conductive or magnetically susceptible objects. Berkshire recommends physical investigations of all EM-31 anomalies to determine their source.

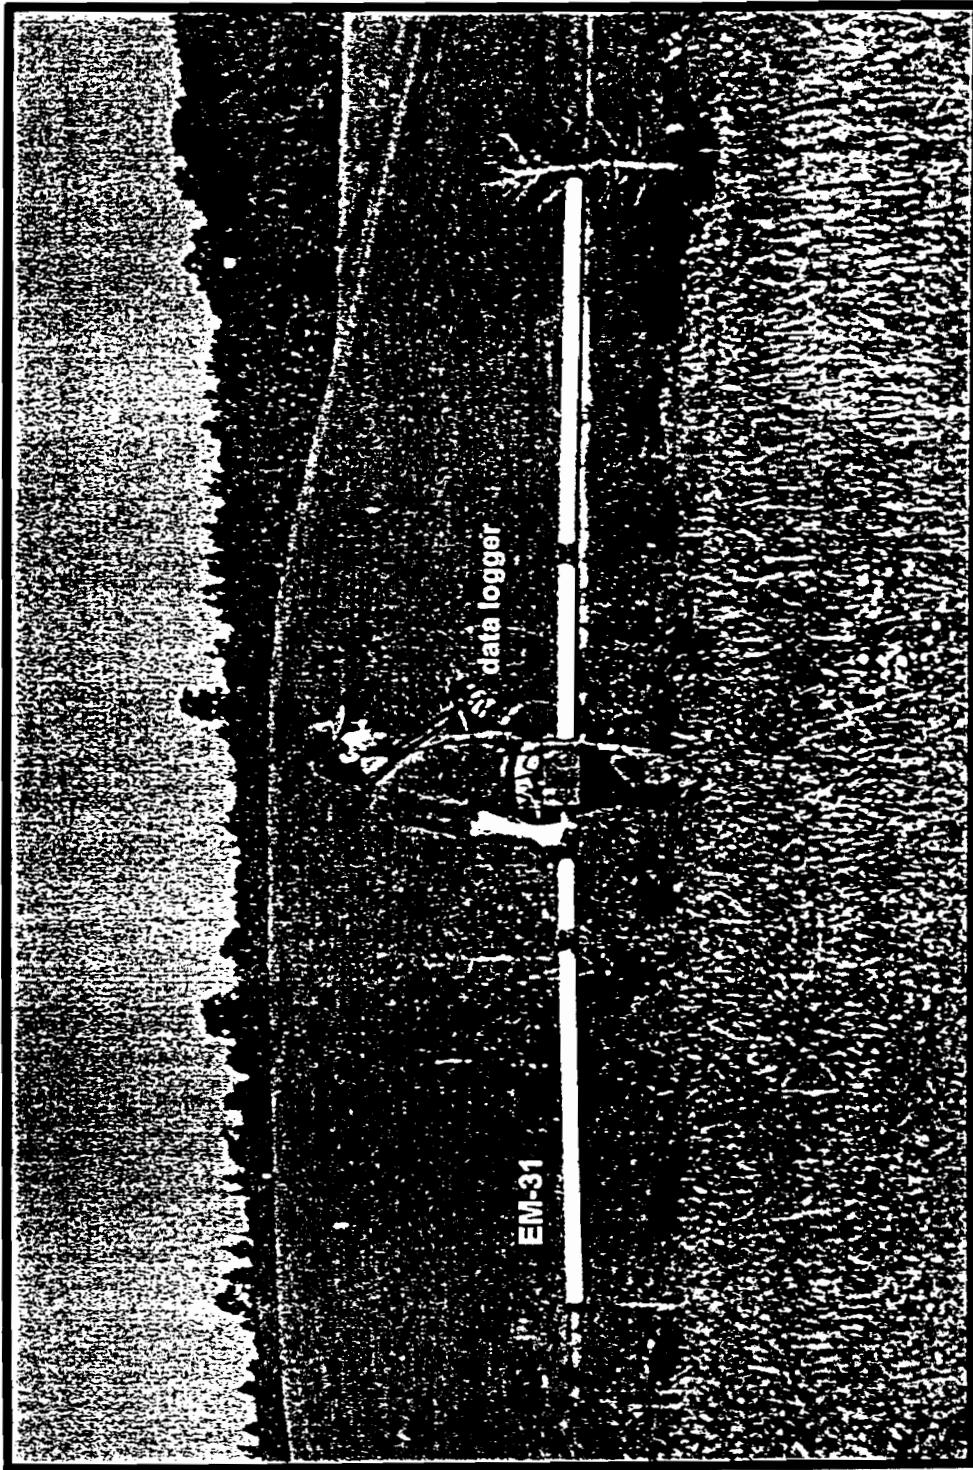

5.0 CLOSING

The field procedures and interpretative methodologies used in this project are consistent with standard, recognized practices in similar geophysical investigations. The correlation of geophysical responses with probable subsurface features is based on the past result of similar surveys although it is possible some variation could exist at this site. This warranty is in lieu of all other warranties either implied or expressed. Berkshire assumes no responsibility for interpretations made by others based on work performed by or recommendations made by Berkshire.

Sincerely,
Berkshire Environmental, Inc.

TP-23	0-3	Uniform black ash/cinders.		
	3-4	Same as above, with lenses of gray to white material, fibrous in spots, some sand and silt-sized material.	SVOCs Metals	
	4-5	Native material - Tan to light brown clayey silt, some rust mottling.		
TP-24	0-1.5	Reworked native material - brown to tan sandy silt and clay.	None.	Seepage just above native material.
	1.5-3.5	Black cinders/ash, some rusted metal debris, some wood fragments.		
	3.5-5	Native material - Tan to light brown clayey silt, some rust mottling.		
TP-25	0-2.5	Reworked native material - brown to dark brown sandy silt and clay.	None.	Seepage just above native material.
	2.5-4	Native material - Tan to light brown clayey silt, some rust mottling.		

**MALCOLM
PIRNIE**

Project:	Wurlitzer Area B	Excavation Dates:	4/20/98
Project No.:	0266-332	Excavation Method:	Backhoe
Client:	NYSDEC	Logged / Checked By:	DER/LES
Location:	North Tonawanda	Test Pit Location #:	TP-26 to TP-32

Test Pit	Depth BGS	Soil Description	Samples	Comments (Include seepage horizons)
TP-26	0-3	Reworked native material - brown to dark brown sandy silt and clay, large concrete pieces at surface.	None.	
	3-5	Native material - Tan to light brown clayey silt, some rust mottling.		
TP-27	0-3	Black cinders/ash with some lenses of reworked native material - brown to dark brown sandy silt and clay, some red and yellow brick.	None.	Seepage just above native material.
	3-4.5	Native material - Tan to light brown clayey silt, some rust mottling.		
TP-28	0-4	Uniform black cinders/ash, some scrap metal at surface.	None.	Seepage just above native material.
	4-5	Native material - Tan to light brown clayey silt, some rust mottling.		
TP-29	0-4	Uniform black cinders/ash.	None.	Seepage just above native material.
	4-5	Native material - Tan to light brown clayey silt, some rust mottling.		
TP-30	0-2	Uniform black cinders/ash with some intermixed tan to brown sandy silt and clay.	None.	Seepage just above native material.
	2-4	Native material - Tan to light brown clayey silt, some rust mottling, some very fine sand.		
TP-31	0-2	Reworked native material - tan clayey silt with rust mottling.	None.	Seepage just above native material.
	2-3	Uniform black cinders/ash.		
	3-4	Native material - Tan to light brown clayey silt, some rust mottling, some very fine sand.		
TP-32	0-1.5	Reworked native material - tan clayey silt with rust mottling.	None.	Seepage just above native material.
	1.5-2.5	Uniform black cinders/ash.		
	2.5-4	Native material - Tan to light brown clayey silt, some rust mottling, some very fine sand.
