RECORD OF DECISION

Crouse-Hinds Landfills
State Superfund Project
Syracuse, Onondaga County
Site No. 734004
March 2011

Prepared by
Division of Environmental Remediation
New York State Department of Environmental Conservation
DECLARATION STATEMENT - RECORD OF DECISION

Crouse-Hinds Landfills
State Superfund Project
Syracuse, Onondaga County
Site No. 734004
March 2011

Statement of Purpose and Basis

This document presents the remedy for the Crouse-Hinds Landfills site, a Class 2 inactive hazardous waste disposal site. The remedial program was chosen in accordance with the New York State Environmental Conservation Law and Title 6 of the Official Compilation of Codes, Rules and Regulations of the State of New York (6 NYCRR) Part 375, and is not inconsistent with the National Oil and Hazardous Substances Pollution Contingency Plan of March 8, 1990 (40CFR300), as amended.

This decision is based on the Administrative Record of the New York State Department of Environmental Conservation (the Department) for the Crouse-Hinds Landfills site and the public's input to the proposed remedy presented by the Department. A listing of the documents included as a part of the Administrative Record is included in Appendix B of the ROD.

Description of Selected Remedy

The elements of the selected remedy are as follows:

1. A remedial design program will be implemented to provide the details necessary for the construction, operation, maintenance, and monitoring of the remedial program.

2. There are three identified hot spots that will be targeted for excavation and off-site disposal. All three areas occur in the North Landfill. One area on the east side includes approximately 750 cubic yards of waste containing PCBs at concentrations of 50 ppm or greater. The other area on the east side includes approximately 4,500 cubic yards of waste that contains elevated solvents. The area on the west side of the North Landfill includes approximately 1,500 cubic yards of oily waste in the vicinity of monitoring well MW-6. All three areas will be characterized, excavated and transported off-site to a TSCA and/or hazardous waste landfill as applicable. Characterization will include design borings to further delineate the hot spot areas. During excavation, the hot spot areas containing oily waste or elevated solvents will be further delineated through visual confirmation, detection of strong odors, measurement of elevated contaminant vapor concentrations, or by otherwise readily implementable methods without the need for laboratory analyses.

3. Both the North and South Landfills will be consolidated to reduce their current area. The consolidated areas will have engineered cap systems designed and constructed in conformance
with the substantive requirements for landfill caps set forth in 6 NYCRR Part 360. The areas to be consolidated will be determined during the design; however, areas to be excavated will include a 50-foot buffer zone area between the South Landfill and Ley Creek and 30-foot buffer zone areas between the landfills and on-site wetlands. If required for cap installation, buffer zones will be established between the landfills and Seventh North Street. This excavated material will be consolidated in the landfills above the water table.

4. Wetland sediment at PCB concentrations greater than 1 ppm and less than 50 ppm will be excavated for consolidation and capping on site with the material discussed above. PCB contaminated sediment at concentrations of 50 ppm or greater will be properly transported off-site for disposal.

5. The excavated wetlands and buffer zones will be restored and maintained per an approved restoration plan developed during the remedial design phase. Buffer zone soils will need to meet the Unrestricted Use Soil Cleanup Objectives set forth in Table 375-6.8(a) of 6 NYCRR Part 375 for a minimum of two feet in depth measured from the finished surface grade. The remaining buffer zone soils will need to meet, at a minimum, the lower of the protection of groundwater or the protection of public health soil cleanup objectives for commercial use as set forth in Table 375-6.8(b) of 6 NYCRR Part 375.

6. Green remediation and sustainability efforts would be considered in the design and implementation of the remedy to the extent practicable, including:

(a) using renewable energy sources;
(b) reducing green house gas emissions;
(c) encouraging low carbon technologies;
(d) conserve natural resources;
(e) increase recycling and reuse of clean materials;
(f) preserve open space and working landscapes; and
(g) design cover systems to be usable for habitat or recreation.

7. Imposition of an institutional control in the form of an environmental easement for the controlled property that will:

(a) require the remedial party or site owner to complete and submit to the Department a periodic certification of institutional and engineering controls in accordance with Part 375-1.8 (h)(3);
(b) allow the use and development of the controlled property for industrial use, although subject to local zoning laws;
(c) restrict the use of groundwater and surface water as a source of potable or process water, without necessary water quality treatment as determined by the Department, NYSDOH or County DOH;
(d) prohibit agriculture or vegetable gardens on the controlled property; and
(e) require compliance with the Department approved Site Management Plan.
8. A Site Management Plan will be required, which includes the following:

(a) an Institutional and Engineering Control Plan that identifies all use restrictions and engineering controls for the site and details the steps and media-specific requirements necessary to assure the following institutional and/or engineering controls remain in place and effective:

Institutional Controls: The Environmental Easement discussed above.

Engineering Controls: The landfill caps and fencing discussed above.

This plan would include, but may not be limited to:

(i) an Excavation Plan which details the provisions for management of future excavations in areas of remaining contamination;
(ii) descriptions of the provisions of the environmental easement including any land use, groundwater and surface water use restrictions;
(iii) provisions for the management and inspection of the identified engineering controls;
(iv) maintaining site access controls and Department notification;
(v) the steps necessary for the periodic reviews and certification of the institutional and/or engineering controls; and
(vi) a provision to evaluate the potential for vapor intrusion for any buildings developed on the site, including provision for implementing actions recommended to address exposures related to soil vapor intrusion.

(b) a Monitoring Plan to assess the performance and effectiveness of the remedy. The plan includes, but would not be limited to:

(i) monitoring of wetlands, groundwater, surface water and sediment to assess the performance and effectiveness of the remedy;
(ii) a schedule of monitoring and frequency of submittals to the Department; and
(iii) monitoring of wetlands and buffer areas to assess restoration success.

9. The remedial party or subsequent property owner will provide a periodic certification of institutional and engineering controls for the site, prepared and submitted by a professional engineer or such other expert, acceptable to the Department, until the Department notifies the property owner in writing that this certification is no longer needed. This submittal will: (a) contain certification that the institutional controls and engineering controls put in place are still in place, and are either unchanged from the previous certification or are compliant with Department-approved modifications; (b) allow the Department access to the site; and (c) state that nothing has occurred that would impair the ability of the control to protect public health or the environment, or constitute a violation or failure to comply with the site management plan unless otherwise approved by the Department.
New York State Department of Health Acceptance

The New York State Department of Health (NYSDOH) concurs that the remedy for this site is protective of human health. 

Declaration

The selected remedy is protective of human health and the environment, complies with State and Federal requirements that are legally applicable or relevant and appropriate to the remedial action to the extent practicable, and is cost effective. This remedy utilizes permanent solutions and alternative treatment or resource recovery technologies, to the maximum extent practicable, and satisfies the preference for remedies that reduce toxicity, mobility, or volume as a principal element. 

MAR 3 1 2011

Date

Dale A. Desnoyers, Director
Division of Environmental Remediation
SECTION 1: SUMMARY AND PURPOSE

The New York State Department of Environmental Conservation (the Department), in consultation with the New York State Department of Health (NYSDOH), has selected a remedy for the above referenced site. The disposal of hazardous wastes at the site has resulted in threats to public health and the environment that would be addressed by the remedy. The disposal or release of hazardous wastes at this site, as more fully described in this document, has contaminated various environmental media. The remedy is intended to attain the remedial action objectives identified for this site for the protection of public health and the environment. This Record of Decision (ROD) identifies the selected remedy, summarizes the other alternatives considered, and discusses the reasons for selecting the remedy.

The New York State Inactive Hazardous Waste Disposal Site Remedial Program (also known as the State Superfund Program) is an enforcement program, the mission of which is to identify and characterize suspected inactive hazardous waste disposal sites and to investigate and remediate those sites found to pose a significant threat to public health and environment.

The Department has issued this document in accordance with the requirements of New York State Environmental Conservation Law and 6 NYCRR Part 375. This document is a summary of the information that can be found in the site-related reports and documents.

SECTION 2: SITE DESCRIPTION AND HISTORY

Location:

The Crouse-Hinds Landfills Site consists of two inactive landfills, referred to as the North and South Landfills. The Site is located in the Town of Salina (North Landfill) and City of Syracuse (South Landfill), Onondaga County, New York.

The North Landfill is bordered along its northern border by vacant land owned by Plaza East, LLC. This vacant land to the north of the North Landfill consists of areas of fill (municipal waste and miscellaneous debris) with woodland cover and wetlands. The North Landfill is bordered to the east by CSX railroad tracks followed by the Crouse-Hinds manufacturing facility. Seventh North Street followed by the South Landfill border the North Landfill to the south. West of the North Landfill are wetlands, also owned by Plaza East, followed by Ley Creek.
The South Landfill is bordered to the north by Seventh North Street followed by the North Landfill. To the east, the South Landfill is bordered by CSX railroad tracks. Undeveloped woods, wetlands and mixed commercial and retail development border the South Landfill to the south. Ley Creek abuts the entire west and northwest boundary of the South Landfill.

Site Features:

The North Landfill is 21.5 acres in size, and the South Landfill is 19.4 acres in size. Seventh North Street is oriented southeast-northwest and separates the two landfills that comprise the site. Adjacent to the North Landfill are on-site wetlands to the east and west, along with an on-site drainage channel to the east. Adjacent to the South Landfill are on-site wetlands to the south and an on-site drainage channel to the east.

Current Zoning:

The Site is currently zoned industrial and is located in an area of mixed usage including light industrial/manufacturing and commercial.

Historical Use:

Prior to the mid-to-late 1950’s the North and South Landfill areas had been occupied by low lying fields, salt marshes and woodlands. From the mid-1950’s to 1989 fill material was placed across various areas of the North and South Landfills.

Beginning in the mid-1950’s, the North Landfill was used for disposal of industrial wastes that were generated at the Crouse-Hinds manufacturing facility. Wastes disposed of in the North Landfill include foundry sand, core butts, floor sweepings, metal buffing and polishing residue, scrap lumber, plastic wastes and paint scrapings, all originating from the facility. Zinc hydroxide sludge generated from the facility's wastewater treatment plant was also disposed of in the North Landfill from 1972 to 1980. Waste disposal was discontinued at the North Landfill in 1989, and it has been inactive since.

In 1960, the company began using the South Landfill for disposal of industrial wastes that were generated at the Crouse-Hinds manufacturing facility. These wastes included foundry molds and core sand, scrap steel drums and shot, fly ash, paint scrapings, garbage and construction and demolition debris. In addition to disposal of wastes by the facility, from 1960 to 1965, the South Landfill also accepted approximately 2,000 cubic yards per week of municipal solid waste from the City of Syracuse. Waste disposal activities were discontinued at the South Landfill in 1969, and the South Landfill has been inactive ever since that time.

Site Geology and Hydrogeology:

The site geology consists of unconsolidated glaciolacustrine and glaciofluvial sediments as described below. A shallow groundwater flow system, located from approximately 6 to 30 below ground surface, in the fill, peat, sand and silt deposits, and a deep confined groundwater...
flow system located in sand and gravel deposits are present at the site. The deep groundwater system is separated from the overlying shallow groundwater system by a continuous confining layer of silt and clay deposits of varying thickness commencing at approximately 30 feet below ground surface.

Groundwater flow in the shallow groundwater system is generally to the west toward Ley Creek. Groundwater flow in the deep groundwater flow system is generally to the east. Groundwater in the deep aquifer exhibits a strong upward vertical gradient and at times exhibits artesian conditions in the deep wells located on the North Landfill.

A site location map is attached as Figure 1.

**SECTION 3: LAND USE AND PHYSICAL SETTING**

The Department may consider the current, intended, and reasonably anticipated future land use of the site and its surroundings when evaluating a remedy for soil remediation. For this site, alternatives (or an alternative) that restrict(s) the use of the site to industrial use as described in Part 375-1.8(g) is/are being evaluated in addition to an alternative which would allow for unrestricted use of the site.

A comparison of the results of the investigation to the appropriate standards, criteria and guidance values (SCGs) for the identified land use and the unrestricted use SCGs for the site contaminants is included in the Tables for the media being evaluated in Exhibit A.

**SECTION 4: ENFORCEMENT STATUS**

Potentially Responsible Parties (PRPs) are those who may be legally liable for contamination at a site. This may include past or present owners and operators, waste generators, and haulers.

The PRPs for the site, documented to date, include:

Cooper Crouse-Hinds

The Department and Cooper Crouse-Hinds entered into a Consent Order on May 14, 2004. The Order obligates the responsible party to implement a PSA/RI/FS remedial program. After the remedy is selected, the Department will approach Cooper Crouse-Hinds to implement the selected remedy.

**SECTION 5: SITE CONTAMINATION**

5.1: **Summary of the Remedial Investigation**

A Remedial Investigation (RI) has been conducted. The purpose of the RI was to define the nature and extent of any contamination resulting from previous activities at the site. The field activities and findings of the investigation are described in the RI Report.
The following general activities are conducted during an RI:

- Research of historical information,
- Geophysical survey to determine the lateral extent of wastes,
- Test pits, soil borings, and monitoring well installations,
- Sampling of waste, surface and subsurface soils, groundwater, and soil vapor,
- Sampling of surface water and sediment,
- Ecological and Human Health Exposure Assessments.

5.1.1: **Standards, Criteria, and Guidance (SCGs)**

The remedy must conform to promulgated standards and criteria that are directly applicable or that are relevant and appropriate. The selection of a remedy must also take into consideration guidance, as appropriate. Standards, Criteria and Guidance are hereafter called SCGs.

To determine whether the contaminants identified in various media are present at levels of concern, the data from the RI were compared to media-specific SCGs. The Department has developed SCGs for groundwater, surface water, sediments, and soil. The NYSDOH has developed SCGs for drinking water and soil vapor intrusion. The tables found in Exhibit A list the applicable SCGs in the footnotes. For a full listing of all SCGs see: [http://www.dec.ny.gov/regulations/61794.html](http://www.dec.ny.gov/regulations/61794.html)

5.1.2: **RI Information**

The analytical data collected on this site includes data for:

- groundwater
- surface water
- soil
- sediment

The data have identified contaminants of concern. A "contaminant of concern" is a hazardous waste that is sufficiently present in frequency and concentration in the environment to require evaluation for remedial action. Not all contaminants identified on the property are contaminants of concern. The nature and extent of contamination and environmental media requiring action are summarized in Exhibit A. Additionally, the RI Report contains a full discussion of the data. The contaminant(s) of concern identified at this site is/are:

- industrial wastes
- benzene
- zinc
- phenol
- 1,4-dichlorobenzene
- chlorobenzene
benzo(a)pyrene  pcb-aroclor 1242  
arsenic  pcb-aroclor 1248  
cadmium  pcb-aroclor 1254  
benz(a)anthracene  pcb-aroclor 1260  
lead  chromium

As illustrated in Exhibit A, the contaminant(s) of concern exceed the applicable SCGs for:

- groundwater
- surface water
- soil
- sediment

5.2: **Interim Remedial Measures**

An interim remedial measure (IRM) is conducted at a site when a source of contamination or exposure pathway can be effectively addressed before issuance of the Record of Decision.

There were no IRMs performed at this site during the RI.

5.3: **Summary of Human Exposure Pathways**

This human exposure assessment identifies ways in which people may be exposed to site-related contaminants. Chemicals can enter the body through three major pathways (breathing, touching or swallowing). This is referred to as exposure.

People are not drinking the contaminated groundwater because the area is served by a public water supply that is not affected by site-related contamination. Also, they are not coming into contact with the groundwater unless they dig deeper than six feet below the ground surface. The potential for direct contact with contaminated surface soils identified in isolated areas of the site is minimized by vegetation that covers the site. People are not expected to come into direct contact with contaminated soil (dirt) or sediment unless they dig below the ground surface or wade through creek and/or wetland sediment.

Volatile organic compounds in the groundwater may move into the soil vapor (air spaces within the soil), which in turn may move into overlying buildings and affect the indoor air quality. This process, which is similar to the movement of radon gas from the subsurface into the indoor air of buildings, is referred to as soil vapor intrusion. Because the site is vacant, the inhalation of site-related contaminants due to soil vapor intrusion does not represent a concern for the site in its current condition. However, the potential exists for people to inhale site-related contaminants in indoor air due to soil vapor intrusion in any future on-site building development and occupancy. An evaluation of the potential for soil vapor intrusion to occur will be completed should the current use of the site change.
5.4: Summary of Environmental Assessment

This section summarizes the assessment of existing and potential future environmental impacts presented by the site. Environmental impacts may include existing and potential future exposure pathways to fish and wildlife receptors, wetlands, groundwater resources, and surface water.

The Fish and Wildlife Resources Impact Analysis (FWRIA) for OU 01, which is included in the RI report, presents a detailed discussion of the existing and potential impacts from the site to fish and wildlife receptors.

No threatened or endangered plant or animal species were observed on the Crouse-Hinds Landfills Site or are believed to inhabit the site. The site supports vegetation and wildlife consistent with terrestrial, wetland and stream corridor cover types.

Contaminants of concern were detected at concentration levels exceeding relevant ecological criteria in shallow and subsurface soil, on-site sediment, surface water and groundwater at the site. While contaminants of concern were detected in the sediment and surface water in Ley Creek, the data demonstrate that the current impacts to Ley Creek are not attributable to the site. Rather, sampling has shown that upstream sources, not associated with this site, are impacting the creek. For example, lead in Ley Creek surface water was detected at concentrations in excess of the New York State surface water quality standard (17.9 ppb) adjacent to the site; however, the highest concentration detected in Ley Creek during the RI was at the upgradient sampling location (84.2 ppb). In addition, sediment concentrations of PAHs, PCBs and metals generally remain consistent from upstream of the landfills to downstream of the landfills indicating that the site is not significantly impacting Ley Creek.

Complete and potentially ecologically-significant pathways to wildlife receptors were identified for each of the media (soil, sediment, groundwater and surface water) sampled at the site. The site is unpaved and exhibits a potential pathway to wildlife receptors through the erosion of contaminated surface soils to onsite wetlands and drainage channels. Contaminated sediment erosion to Ley Creek is minimized by sediment check dams in a drainage channel to the wetland east of the North Landfill and by the prior removal of a 36-inch culvert from a drainage channel between Ley Creek and the wetland adjacent to the South Landfill. Both soil and waste provide a complete pathway to burrowing wildlife. Surface water and sediments in drainage channels and wetlands at the site provide a complete pathway to aquatic organisms and their predators. Surface water runoff to Ley Creek provides a potential pathway to aquatic organisms and their predators. Groundwater seepage to surface water onsite provides a potential pathway to aquatic organisms.

SECTION 6: SUMMARY OF THE EVALUATION OF ALTERNATIVES

To be selected the remedy must be protective of human health and the environment, be cost-effective, comply with other statutory requirements, and utilize permanent solutions, alternative technologies or resource recovery technologies to the maximum extent practicable. The remedy must also attain the remedial action objectives identified for the site, which are presented in
Exhibit B. Potential remedial alternatives for the Site were identified, screened and evaluated in the feasibility study (FS) report.

A summary of the remedial alternatives that were considered for this site is presented in Exhibit C. Cost information is presented in the form of present worth, which represents the amount of money invested in the current year that would be sufficient to cover all present and future costs associated with the alternative. This enables the costs of remedial alternatives to be compared on a common basis. As a convention, a time frame of 30 years is used to evaluate present worth costs for alternatives with an indefinite duration. This does not imply that operation, maintenance, or monitoring would cease after 30 years if remediation goals are not achieved. A summary of the Remedial Alternatives Costs is included as Exhibit D.

6.1: Evaluation of Remedial Alternatives

The criteria to which potential remedial alternatives are compared are defined in 6 NYCRR Part 375. A detailed discussion of the evaluation criteria and comparative analysis is included in the FS report.

The first two evaluation criteria are termed "threshold criteria" and must be satisfied in order for an alternative to be considered for selection.

1. Protection of Human Health and the Environment. This criterion is an overall evaluation of each alternative's ability to protect public health and the environment.

2. Compliance with New York State Standards, Criteria, and Guidance (SCGs). Compliance with SCGs addresses whether a remedy will meet environmental laws, regulations, and other standards and criteria. In addition, this criterion includes the consideration of guidance which the Department has determined to be applicable on a case-specific basis.

The next six "primary balancing criteria" are used to compare the positive and negative aspects of each of the remedial strategies.

3. Long-term Effectiveness and Permanence. This criterion evaluates the long-term effectiveness of the remedial alternatives after implementation. If wastes or treated residuals remain on-site after the selected remedy has been implemented, the following items are evaluated: 1) the magnitude of the remaining risks, 2) the adequacy of the engineering and/or institutional controls intended to limit the risk, and 3) the reliability of these controls.

4. Reduction of Toxicity, Mobility or Volume. Preference is given to alternatives that permanently and significantly reduce the toxicity, mobility or volume of the wastes at the site.

5. Short-term Impacts and Effectiveness. The potential short-term adverse impacts of the remedial action upon the community, the workers, and the environment during the construction and/or implementation are evaluated. The length of time needed to achieve the remedial objectives is also estimated and compared against the other alternatives.
6. **Implementability.** The technical and administrative feasibility of implementing each alternative are evaluated. Technical feasibility includes the difficulties associated with the construction of the remedy and the ability to monitor its effectiveness. For administrative feasibility, the availability of the necessary personnel and materials is evaluated along with potential difficulties in obtaining specific operating approvals, access for construction, institutional controls, and so forth.

7. **Cost-Effectiveness.** Capital costs and annual operation, maintenance, and monitoring costs are estimated for each alternative and compared on a present worth basis. Although cost-effectiveness is the last balancing criterion evaluated, where two or more alternatives have met the requirements of the other criteria, it can be used as the basis for the final decision.

8. **Land Use.** When cleanup to pre-disposal conditions is determined to be infeasible, the Department may consider the current, intended, and reasonable anticipated future land use of the site and its surroundings in the selection of the soil remedy.

The final criterion, Community Acceptance, is considered a "modifying criterion" and is taken into account after evaluating those above. It is evaluated after public comments on the Proposed Remedial Action Plan have been received.

9. **Community Acceptance.** Concerns of the community regarding the investigation, the evaluation of alternatives, and the PRAP are evaluated. A responsiveness summary will be prepared that describes public comments received and the manner in which the Department will address the concerns raised. If the selected remedy differs significantly from the proposed remedy, notices to the public will be issued describing the differences and reasons for the changes.

### 6.2: Elements of the Remedy

The basis for the Department's remedy is set forth at Exhibit E.

The estimated present worth cost to implement the remedy is 12500000. The cost to construct the remedy is estimated to be 11800000 and the estimated average annual cost is 48000.

The elements of the selected remedy are as follows:

1. A remedial design program will be implemented to provide the details necessary for the construction, operation, maintenance, and monitoring of the remedial program.

2. There are three identified hot spots that will be targeted for excavation and off-site disposal. All three areas occur in the North Landfill. One area on the east side includes approximately 750 cubic yards of waste containing PCBs at concentrations of 50 ppm or greater. The other area on the east side includes approximately 4,500 cubic yards of waste that contains elevated solvents. The area on the west side of the North Landfill includes approximately 1,500 cubic yards of oily waste in the vicinity of monitoring well MW-6. All three areas will be characterized, excavated and transported off-site to a TSCA and/or hazardous waste landfill as
applicable. Characterization will include design borings to further delineate the hot spot areas. During excavation, the hot spot areas containing oily waste or elevated solvents will be further delineated through visual confirmation, detection of strong odors, measurement of elevated contaminant vapor concentrations, or by otherwise readily implementable methods without the need for laboratory analyses.

3. Both the North and South Landfills will be consolidated to reduce their current area. The consolidated areas will have engineered cap systems designed and constructed in conformance with the substantive requirements for landfill caps set forth in 6 NYCRR Part 360. The areas to be consolidated will be determined during the design; however, areas to be excavated will include a 50-foot buffer zone area between the South Landfill and Ley Creek and 30-foot buffer zone areas between the landfills and on-site wetlands. If required for cap installation, buffer zones will be established between the landfills and Seventh North Street. This excavated material will be consolidated in the landfills above the water table.

4. Wetland sediment at PCB concentrations greater than 1 ppm and less than 50 ppm will be excavated for consolidation and capping on site with the material discussed above. PCB contaminated sediment at concentrations of 50 ppm or greater will be properly transported off-site for disposal.

5. The excavated wetlands and buffer zones will be restored and maintained per an approved restoration plan developed during the remedial design phase. Buffer zone soils will need to meet the Unrestricted Use Soil Cleanup Objectives set forth in Table 375-6.8(a) of 6 NYCRR Part 375 for a minimum of two feet in depth measured from the finished surface grade. The remaining buffer zone soils will need to meet, at a minimum, the lower of the protection of groundwater or the protection of public health soil cleanup objectives for commercial use as set forth in Table 375-6.8(b) of 6 NYCRR Part 375.

6. Green remediation and sustainability efforts would be considered in the design and implementation of the remedy to the extent practicable, including:

(a) using renewable energy sources;
(b) reducing green house gas emissions;
(c) encouraging low carbon technologies;
(d) conserve natural resources;
(e) increase recycling and reuse of clean materials;
(f) preserve open space and working landscapes; and
(g) design cover systems to be usable for habitat or recreation

7. Imposition of an institutional control in the form of an environmental easement for the controlled property that will:

(a) require the remedial party or site owner to complete and submit to the Department a periodic certification of institutional and engineering controls in accordance with Part 375-1.8 (h)(3);
(b) allow the use and development of the controlled property for industrial use, although subject to local zoning laws;
(c) restrict the use of groundwater and surface water as a source of potable or process water, without necessary water quality treatment as determined by the Department, NYSDOH or County DOH;
(d) prohibit agriculture or vegetable gardens on the controlled property; and
(e) require compliance with the Department approved Site Management Plan

8. A Site Management Plan will be required, which includes the following:

(a) an Institutional and Engineering Control Plan that identifies all use restrictions and engineering controls for the site and details the steps and media-specific requirements necessary to assure the following institutional and/or engineering controls remain in place and effective:

Institutional Controls: The Environmental Easement discussed above.

Engineering Controls: The landfill caps and fencing discussed above.

This plan would include, but may not be limited to:

(i) an Excavation Plan which details the provisions for management of future excavations in areas of remaining contamination;
(ii) descriptions of the provisions of the environmental easement including any land use, groundwater and surface water use restrictions;
(iii) provisions for the management and inspection of the identified engineering controls;
(iv) maintaining site access controls and Department notification;
(v) the steps necessary for the periodic reviews and certification of the institutional and/or engineering controls; and
(vi) a provision to evaluate the potential for vapor intrusion for any buildings developed on the site, including provision for implementing actions recommended to address exposures related to soil vapor intrusion.

(b) a Monitoring Plan to assess the performance and effectiveness of the remedy. The plan includes, but would not be limited to:

(i) monitoring of wetlands, groundwater, surface water and sediment to assess the performance and effectiveness of the remedy;
(ii) a schedule of monitoring and frequency of submittals to the Department; and
(iii) monitoring of wetlands and buffer areas to assess restoration success.

9. The remedial party or subsequent property owner will provide a periodic certification of institutional and engineering controls for the site, prepared and submitted by a professional engineer or such other expert, acceptable to the Department, until the Department notifies the property owner in writing that this certification is no longer needed. This submittal will: (a) contain certification that the institutional controls and engineering controls put in place are still in place, and are either unchanged from the previous certification or are compliant with Department-approved modifications; (b) allow the Department access to the site; and (c) state that nothing has occurred that would impair the ability of the control to protect public health or
the environment, or constitute a violation or failure to comply with the site management plan unless otherwise approved by the Department.
Exhibit A

Nature and Extent of Contamination

This section describes the findings of the Remedial Investigation. As described in the RI report, waste/source materials were identified at the site and are impacting groundwater, soil, surface water and/or sediment.

Waste/Source Areas

Wastes are defined in 6 NYCRR Part 375-1.2 (aw) and include solid, industrial and/or hazardous wastes. Source Areas are defined in 6 NYCRR Part 375-1.2 (au). Source areas are areas of concern at a site where substantial quantities of contaminants are found which can migrate and release significant levels of contaminants to another environmental medium. Wastes and/or Source areas identified at the site include the North and South Landfills (see Figure 2).

The North Landfill is predominantly industrial fill ranging in thickness from 3 to 17 feet and consisting primarily of foundry sand, foundry core butts, foundry molds, metal debris, wood debris and miscellaneous industrial debris. The industrial fill was generally black in color and had an oily type nature. Varying amounts of municipal waste (glass, bottles, plastic debris, metal cans, paper, etc.) were observed along the northern/northeastern property boundary. The volume of waste in the North Landfill is estimated at 223,000 cubic yards.

PID readings in the majority of test pits were generally low indicating that VOC impacts in fill materials located across the North Landfill were generally low. However, there were three hot spots identified in the North Landfill. One area on the east side includes approximately 750 cubic yards of waste containing PCBs at concentrations of 50 ppm or greater. The other area on the east side includes approximately 4,500 cubic yards of waste that exhibit elevated solvent concentrations. The area on the west side of the North Landfill includes approximately 1,500 cubic yards of oily waste in the vicinity of monitoring well MW-6.

The South Landfill contains industrial fill and municipal waste ranging in thickness from 0 to 19 feet. The industrial fill is consistent with that found in the North Landfill. The municipal waste consists of glass, bottles, plastic debris, metal cans, paper and general municipal refuse. The fill along the western boundary with Ley Creek is all municipal waste and no industrial fill. The volume of waste in the South Landfill is estimated at 220,000 cubic yards.

The waste/source areas identified will be addressed in the remedy selection process.

Below, the section describes the findings for all environmental media that were evaluated. As described in the RI report, groundwater, soil, surface water and sediment samples were collected to characterize the nature and extent of contamination.

For each medium sampled, a table summarizes the findings of the investigation. The tables present the range of contamination found at the site in the media and compare the data with the applicable SCGs for the site. The contaminants are arranged into four categories; volatile organic compounds (VOCs), semivolatile organic compounds (SVOCs), pesticides/polychlorinated biphenyls (PCBs), and inorganics (metals). For comparison purposes, the SCGs are provided for each medium that allows for unrestricted use. For soil, if applicable, the Restricted Use SCGs identified in Section 4 are also presented.
Groundwater

A shallow groundwater flow system, located from approximately 6 to 30 below ground surface, in the fill, peat and associated mixed deposits, and a deep confined groundwater flow system located in sand and gravel deposits are present at the site. The deep groundwater system is separated from the overlying shallow groundwater system by a continuous confining layer of silt and clay deposits of varying thickness commencing at approximately 30 feet below ground surface.

Groundwater flow in the shallow groundwater system is generally to the west toward Ley Creek. Groundwater flow in the deep groundwater flow system is generally to the east. Groundwater in the deep aquifer exhibits a strong upward vertical gradient and at times exhibits artesian conditions in the deep wells located on the North Landfill.

Groundwater samples were collected from on-site monitoring wells in July 2004 (nineteen wells), November 2005 (twenty-three wells) and December 2007 (twenty-six wells).

- **a** - ppb: parts per billion, which is equivalent to micrograms per liter, ug/L, in water.

The analytical data for shallow groundwater samples collected on the North Landfill indicate that shallow groundwater beneath the North Landfill has contaminant concentrations above NYSDEC Class GA groundwater standards for VOCs (e.g., benzene, chlorobenzene and 1,4-dichlorobenzene), SVOCs (e.g., total phenols) and metals (primarily iron). The analytical data for shallow groundwater samples collected on the South Landfill indicate that shallow groundwater beneath the South Landfill has not been impacted by VOCs or SVOCs and has been minimally, and infrequently, impacted by phenols and limited metals at concentrations slightly in excess of the NYSDEC Class GA groundwater standards. No pesticides, PCBs or cyanide were detected in the shallow groundwater at either landfill.

The analytical data for deep groundwater samples collected on the North and South Landfills indicate no reproducible detections of VOCs, SVOCs, or total phenols. Metals (primarily aesthetic water quality criteria for iron) were detected at concentrations slightly in excess of the NYSDEC Class GA groundwater standards. No pesticides, PCBs or cyanide were detected in the deep groundwater.

Based on the findings of the RI, the disposal of hazardous waste has resulted in the localized contamination of groundwater on-site. While groundwater migrates off-site, there was no discernable impact detected off-site (e.g., to
Ley Creek) from site groundwater. The site contaminants that are considered to be the primary contaminants of concern which will drive the remediation of groundwater to be addressed by the remedy selection process are: total phenols, benzene, chlorobenzene and 1,4-dichlorobenzene (see Figure 3). The iron found in groundwater was found in both the shallow aquifer (site impacted aquifer) and deep groundwater (non-impacted aquifer), and appears to be ubiquitous to the area. Therefore, iron in groundwater is not considered a site specific contaminant of concern.

**Soil**

Shallow and subsurface soil samples were collected at the site during the RI. Shallow soil samples were collected from a depth of 0-6 inches. Subsurface soil samples were collected from a depth of 2 - 18 feet to assess soil contamination impacts to groundwater. The results indicate that soils at the site in the waste masses exceed the unrestricted SCGs for volatile and semi-volatile organics, PCBs/pesticides and metals. The results indicate that soils along the eastern property boundary of both landfills along a strip of land between the wetlands and the railroad property exceed the unrestricted SCGs for PCBs.

[^a]: ppm: parts per million, which is equivalent to milligrams per kilogram, mg/kg, in soil;
[^b]: SCG: Part 375-6.8(a), Unrestricted Soil Cleanup Objectives.
[^c]: SCG: Part 375-6.8(b), Restricted (Industrial Use) Soil Cleanup Objectives.
[^d]: SCG: Part 375-6.8(b), Restricted Soil Cleanup Objectives, Protection of Groundwater – used for the primary contaminants of concern listed in the groundwater section above.

The primary soil contaminants are benzene, benzo(a)pyrene, phenol and metals (arsenic and cadmium) associated with disposal of wastes in the landfill. In addition, PCB contamination exists in soil along the eastern boundary of the site (see Figure 4).

Based on the findings of the Remedial Investigation, the disposal of hazardous waste has resulted in the contamination of soil. Protection of groundwater SCOs are also exceeded for benzene, chlorobenzene and phenol. The site contaminants identified in soil which are considered to be the primary contaminants of concern, to be addressed by the remedy selection process are, benzene, benzo(a)pyrene, phenol, metals (arsenic and cadmium) and PCBs.
Surface Water

Surface water samples were collected during the RI in Ley Creek from upstream of the site, adjacent to the site and downstream of the site. Surface water samples were also collected from on-site wetlands and drainage channels. The samples were collected to assess the surface water conditions on and off-site. The results indicate that contaminants in surface water on-site in wetlands and drainage swales exceed the Department’s SCG for methylene chloride, benz(a)anthracene, benzo(a)pyrene and metals (aluminum, cadmium, chromium, copper, iron, lead and zinc). Surface water quality was generally consistent and below standards in Ley Creek from upstream to downstream indicating that the site does not currently impact Ley Creek surface water. Lead in Ley Creek surface water was detected at concentrations in excess of the New York State surface water quality standard (17.9 ppb) adjacent to the site; however, the highest concentration (84.2 ppb) detected in Ley Creek during the RI was at the upgradient sampling location (see Figure 5). PCBs were detected in only one surface water sample (i.e., upstream in Ley Creek).

Based on the findings of the Remedial Investigation, the disposal of hazardous waste has resulted in the contamination of on-site surface water in wetlands and drainage swales. The site contaminants that are considered to be the primary contaminants of concern which will drive the remediation of surface water to be addressed by the remedy selection process are SVOCs (benz(a)anthracene and benzo(a)pyrene) and metals (cadmium, lead and zinc). The iron found in the wetlands and drainage swales surface water was also found in groundwater, including deep groundwater not impacted by the site and appears to be ubiquitous. Therefore, iron in surface water is not considered a site specific contaminant of concern.

**Sediments**

Sediment samples were collected during the RI in Ley Creek from upstream of the site, adjacent to the site and downstream of the site. Sediment samples were also collected from on-site wetlands and drainage channels. The samples were collected to assess the potential for impacts to on-site wetlands and drainage channel sediment, and Ley Creek sediment, from the site. The results indicate that sediment in the on-site wetlands and on-site drainage channels exceed the Department’s SCGs for sediments for benz(a)anthracene, PCBs and metals (arsenic, cadmium, chromium, iron, lead, manganese, mercury, nickel, silver and zinc). In Ley Creek, sediment concentrations exceed criteria for several PAHs (e.g., benzo(a)pyrene, benzo(k)fluoranthene), PCBs and several metals (e.g., silver, nickel, lead); however, sediment quality was generally consistent in Ley Creek from upstream (e.g., SED-4) to downstream indicating that the site does not currently impact Ley Creek sediment (see figure 6).

a - ppm: parts per million, which is equivalent to milligrams per kilogram, mg/kg, in sediment;
b - SCG: The Department's “Technical Guidance for Screening Contaminated Sediments.”
c – Site Derived Value: Previously selected sediment clean-up goal at New York State hazardous waste sites.
NA – Not Applicable

The primary wetlands and drainage swales sediment contaminants are PCBs and metals, such as cadmium, chromium, lead and zinc, associated with the historic waste disposal at the landfills. The iron found in sediment was also found in groundwater, including deep groundwater not impacted by the site and appears to be ubiquitous. Therefore, iron in sediment is not considered a site specific contaminant of concern.

Based on the findings of the Remedial Investigation, the disposal of hazardous waste has resulted in the contamination of sediment in on-site wetlands and drainage swales. The site contaminants that are considered to be the primary contaminants of concern which will drive the remediation of sediment to be addressed by the remedy selection process are PCBs and metals, such as cadmium, chromium, lead and zinc.
Exhibit B

SUMMARY OF THE REMEDIATION OBJECTIVES

The objectives for the remedial program have been established through the remedy selection process stated in 6 NYCRR Part 375. The goal for the remedial program is to restore the site to pre-disposal conditions to the extent feasible. At a minimum, the remedy shall eliminate or mitigate all significant threats to public health and the environment presented by the contamination identified at the site through the proper application of scientific and engineering principles.

The remedial objectives for this site are:

Public Health Protection

*Groundwater*
- Prevent people from drinking groundwater with contaminant levels exceeding drinking water standards.
- Prevent contact with contaminated groundwater.
- Prevent potential for inhalation of contaminants volatilizing from the groundwater.

*Soil*
- Prevent ingestion/direct contact with contaminated soil.
- Prevent potential for inhalation of contaminants volatilizing from the soil.

*Surface water*
- Prevent people from drinking surface water impacted by contaminants.
- Prevent contact with contaminants from impacted water bodies.

*Sediment*
- Prevent direct contact with contaminated sediments.

Environmental Protection

*Groundwater*
- Restore the groundwater aquifer to meet ambient groundwater quality criteria, to the extent feasible.
- Prevent discharge of contaminated groundwater to surface water.

*Soil*
- Prevent migration of contaminants that would result in groundwater or surface water contamination.
- Prevent impacts to biota from ingestion/direct contact with soil causing toxicity or impacts from bioaccumulation through the terrestrial food chain.

*Surface Water*
- Restore surface water to ambient water quality criteria for the contaminant of concern, to the extent feasible.
- Prevent impacts to biota from ingestion/direct contact with surface water causing toxicity and impacts from bioaccumulation through marine and aquatic food chain.
Sediment

- Prevent releases of contaminants from sediment that would result in surface water levels in excess of ambient water quality criteria.
- Prevent impacts to biota from ingestion/direct contact with sediments causing toxicity and impacts from bioaccumulation through marine and aquatic food chain.
Exhibit C

Description of Remedial Alternatives

The following alternatives were considered based on the remedial action objectives (see Exhibit B) to address the contaminated media identified at the site as describe in Section 5:

Alternative 1: No Action

The No Action Alternative is evaluated as a procedural requirement and as a basis for comparison. This alternative leaves the site in its present condition and does not provide any additional protection to public health and the environment.

Alternative 2: Restoration to Pre-Disposal or Unrestricted Conditions

This alternative achieves all of the SCGs discussed in Section 6.1.1, and the soil meets the unrestricted soil cleanup objectives listed in Part 375-6.8 (a). This alternative includes the removal of all waste and contaminated fill above the unrestricted soil cleanup objectives and the removal of all contaminated sediments for off-site disposal. The landfill areas would be backfilled to 7th North Street grade, and the wetlands areas would be restored. Because contaminant removal would be complete, there would be no institutional controls, fencing or long-term monitoring.

The volume of impacted sediment calculated for each area is 11,400 cubic yards for the North Landfill wetlands and 14,750 cubic yards for the South Landfill wetlands. Of this volume, 1,500 cubic yards contains PCBs at concentrations of 50 ppm or greater and would be transported to a TSCA landfill. The remainder of the contaminated sediment would be transported to a solid waste landfill.

For landfill removal, the volume of waste and contaminated fill calculated is approximately 220,000 cubic yards for each of the North and South Landfills. Of this volume, approximately 750 yards contain greater than 50 ppm PCBs and would be transported to a TSCA landfill. The remainder of the waste contaminated fill would be transported to a solid waste landfill.

This alternative would take approximately one year to design and five years to implement.

Capital Cost: ................................................................. $44,100,000

Alternative 3: Consolidation/Capping and Groundwater Collection via Pumping Wells with On-Site Groundwater Treatment/Disposal

Consolidation/capping refers to the remedial action whereby contaminated wastes, soil, sediment and debris would be excavated and characterized. Excavated material that exceeds the criteria for relocation and capping on site would be either sent off-site for disposal or treated. Excavated material that meets the criteria for relocation and capping on site would be consolidated above the water table and covered. The consolidated areas would have engineered cap systems designed and constructed in conformance with the substantive requirements of 6 NYCRR Part 360 solid waste regulations. A long-term monitoring program would be developed to monitor groundwater and ensure the effectiveness of the engineered cap systems and appropriate storm water management systems. Site control measures (e.g., fencing) would be considered as needed.
Approximately 26,000 cubic yards of sediments from on-site wetlands above 1.0 ppm PCBs and below 50 ppm PCBs would be excavated and consolidated on-site as described above. Approximately 1,500 cubic yards of sediments at concentrations of 50 ppm and above would be excavated and transported off-site for disposal at a TSCA landfill. The wetlands and related drainage channels would be restored via a wetland restoration plan developed during the design.

A buffer zone of 50 feet between Ley Creek and any landfill waste and 30 feet between wetland areas and any landfill waste would be created. Waste within these buffer zones would be removed and consolidated on-site for subsequent capping as described above. For the North and South Landfills, the approximate volume of waste to be consolidated from the buffer zones would be 10,000 and 18,000 cubic yards, respectively.

Engineered cap systems designed and constructed in conformance with the substantive requirements of 6 NYCRR Part 360 solid waste regulations would be installed over the consolidated North and South Landfills. The consolidated waste footprint is estimated to be approximately 14 acres for the North Landfill and 12 acres for the South Landfill. See Figure 7 for the sediment and soil excavation areas, buffer zone areas and cap areas.

Capture of shallow groundwater flow toward Ley Creek would be accomplished through the installation and operation of nine (9) extraction wells placed along the western boundaries of the landfills. Groundwater would be treated on-site to meet discharge criteria either via a new water treatment plant or via the existing wastewater treatment system at the Crouse-Hinds facility.

Since soil at the site would still contain chemical contaminants at concentrations exceeding unrestricted soil cleanup objectives, this alternative includes an environmental easement that would include institutional controls, such as groundwater and land use restrictions and a Site Management Plan (SMP), and engineering controls, such as the engineered caps, and periodic certifications. The SMP would be prepared to: (1) identify known locations of any remaining impacted soil at the site; (2) establish appropriate controls for future disturbances of site soil; (3) set forth the inspection and maintenance activities for perimeter fencing (if needed), the groundwater collection and treatment system and cap materials; and (4) establish protocols and frequencies for media monitoring activities. The SMP would be a means to address potential future soil excavation and potential future exposure to soil vapor (e.g., a soil vapor intrusion evaluation would be completed prior to any buildings being developed on the site).

This alternative would take approximately one year to design and two years to implement. As on-site waste was disposed of below the water table, this waste would continue to locally impact on-site groundwater for the foreseeable future; however, the mitigation of future potential impacts to Ley Creek via groundwater would occur due to remedy implementation.

Present Worth: ............................................................................................................................ $13,500,000
Capital Cost: ............................................................................................................................... $11,100,000
Annual Costs: ................................................................................................................................... $155,000

Alternative 4: Consolidation/Capping and Hotspot Removal

This alternative includes most of the same components as Alternative 3 (institutional controls, fencing, groundwater and surface water monitoring, sediment and waste consolidation and landfill capping). However, instead of installing and operating a groundwater extraction and treatment system, hotspot areas within the North Landfill would be excavated for off-site disposal. It is intended that the removal of the landfill hotspots under Alternative 4,
which serve as continuing sources for most of the groundwater contamination, would eliminate the need for active remediation of the groundwater included under Alternative 3.

There are three identified hot spots that would be targeted for excavation and off-site disposal as shown on Figure 7. All three areas occur in the North Landfill. One area on the east side includes approximately 750 cubic yards of waste containing PCBs at concentrations of 50 ppm or greater. The other area on the east side includes approximately 4,500 cubic yards of waste that contains elevated solvents. The area on the west side of the North Landfill includes approximately 1,500 cubic yards of oily waste in the vicinity of monitoring well MW-6. All three areas would be characterized, excavated and transported off-site to a TSCA and/or hazardous waste landfill as applicable.

Since soil at the site would still contain chemical contaminants at concentrations exceeding unrestricted soil cleanup objectives, this alternative includes an environmental easement that would include institutional controls, such as groundwater and land use restrictions and a Site Management Plan (SMP); engineering controls, such as the engineered caps; and periodic certifications. The SMP would be prepared to: (1) identify known locations of any remaining impacted soil at the site; (2) establish appropriate controls for future disturbances of site soil; (3) set forth the inspection and maintenance activities for perimeter fencing (if needed) and cap materials; and (4) establish protocols and frequencies for media monitoring activities. The SMP would be a means to address potential future soil excavation and potential future exposure to soil vapor (e.g., a soil vapor intrusion evaluation would be completed prior to any buildings being developed on the site).

This alternative would take approximately one year to design and two years to implement.

*Present Worth:* $12,500,000  
*Capital Cost:* $11,800,000  
*Annual Costs:* $48,000

SUMMARY OF THE PROPOSED REMEDY

The Department is proposing Alternative 4, Consolidation/Capping and Hotspot Removal, as the remedy for this site. The elements of this remedy are described at the end of this section. Also, see Figure 7.

Basis for Selection

The proposed remedy is based on the results of the RI and the evaluation of alternatives.

Alternative 4 is being proposed because, as described below, it satisfies the threshold criteria and provides the best balance of the balancing criterion described in Exhibit C. It would achieve the remediation goals for the site by consolidating and capping contaminated soils, sediment and waste, and excavating hotspot areas for off-site disposal. Excavation and off-site disposal of hotspot areas would significantly reduce their source to localized groundwater contamination in the vicinity of these hotspot areas. Alternative 4 addresses the source of the sediment and surface water contamination, and addresses direct contact with contaminated soil and waste, which are the most significant threats to public health and the environment. In addition, the environmental easement would further reduce the potential for exposures at the site by restricting the site's future use to industrial, prohibiting access to groundwater, preventing unauthorized soil excavations, and requiring that a soil vapor intrusion evaluation be completed prior to any buildings being developed on the site.

Alternative 1 (No Action) does not provide any additional protection to public health and the environment and will not be evaluated further. Alternative 2, by removing all soil contaminated above the "unrestricted" soil cleanup objective, meets the threshold criteria. Alternatives 3 and 4 also comply with these criteria, but to a lesser degree of removal. Because Alternatives 2, 3, and 4 satisfy the threshold criteria, the remaining criteria are particularly important in selecting a final remedy for the site.

Alternatives 2 through 4 all have short-term impacts which could easily be controlled; however, Alternatives 2 has the greatest short-term impacts with little additional protection. The time needed to achieve the remediation goals is the shortest for Alternatives 3 and 4. Alternative 2 takes the longest to achieve the remediation goals.

Long-term effectiveness is best accomplished by Alternative 2, followed by Alternative 4, and finally Alternative 3. Alternative 2 would result in the full removal of waste from the site, and would not require an environmental easement or long-term monitoring. Alternative 4 would result in the removal of the main sources of localized groundwater contamination. Alternatives 3 and 4 would remove direct contact with contamination through consolidation and capping. Alternatives 3 and 4 would require an environmental easement and long-term monitoring.

Alternative 2, excavation and off-site disposal, reduces the toxicity, mobility and volume of on-site waste by transferring the material to an approved off-site location. However, depending on the disposal facility, the volume of the material may not be reduced. Alternatives 3 and 4 require the excavation and consolidation of approximately 54,000 and 61,000 cubic yards of contaminated soil and sediment, respectively. Although the volume of the contaminated soils/sediments is not reduced, the contaminated soils/sediments would be excavated and placed above the water table in the consolidation area reducing their mobility. In relation to Alternative 3, Alternative 4 reduces the toxicity, mobility and volume of on-site waste by transferring the hotspot material, approximately 6,750 cubic yards, to an approved off-site disposal facility.
Alternatives 3 and 4 are favorable in that they are readily implementable. Alternative 2 is also implementable, but the volume of soil excavated under this alternative would necessitate increased truck traffic on local roads for several years.

The costs of the alternatives vary significantly. With its large volume of soil to be handled, Alternative 2 (excavation and off-site disposal) would have the highest present worth cost. Consolidation and capping, with either groundwater collection and treatment or hotspot removal (Alternatives 3 and 4), would be much less expensive than Alternative 2, yet it would provide virtually equal protection to public health and the environment. The present worth costs of Alternatives 3 and 4 are similar to each other. The long-term maintenance cost of the cap and groundwater collection and treatment system with Alternative 3 would be higher than long-term maintenance cost of the cap under Alternative 4.

Alternative 2 would remove the contaminated soil permanently. Notwithstanding the residual contamination with Alternatives 3 and 4, anticipated site uses would be readily accommodated with the implementation of a Site Management Plan.
